What we know
What we don't know

Some warning statistics sound and are good

NOAA forecasts are getting better.

Average lead times are up to about 12 minutes

Missed tornadoes are down to 25%

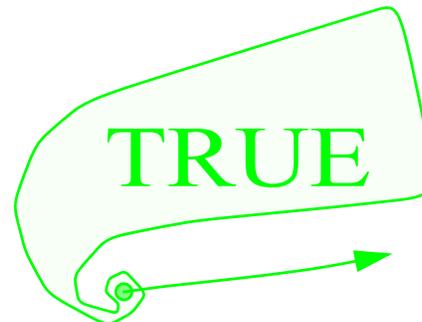

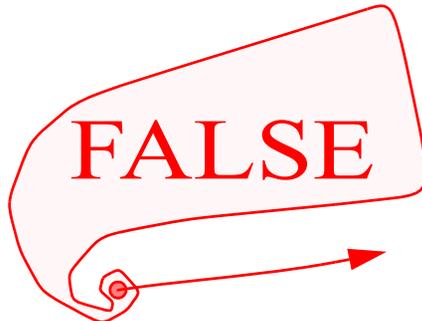

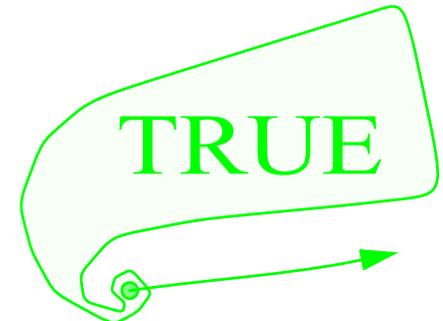

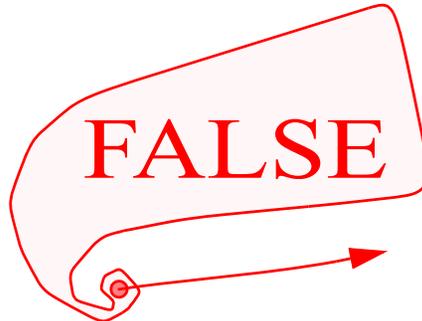

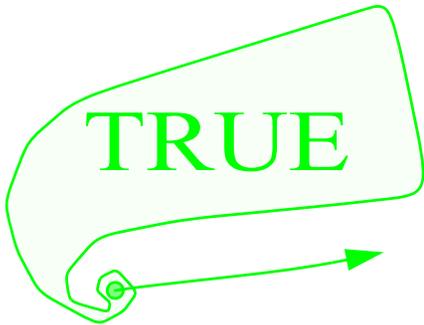

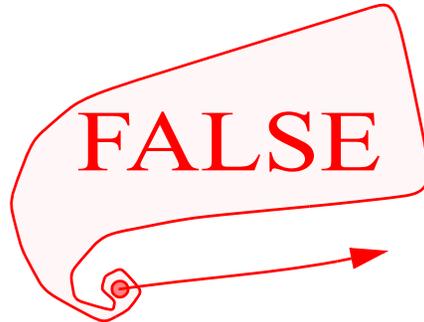

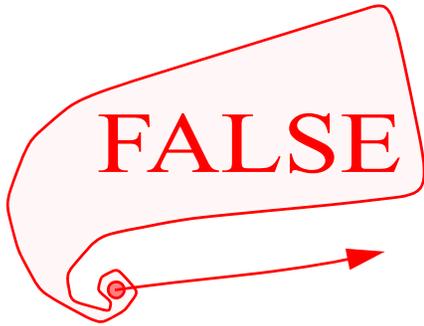

But, the full picture is not so bright

1. Very high false alarm rates
2. No intensity warnings
3. No length of track forecasts
4. 12 minutes is not much time

We don't know **When, Where** tornadoes form

Warning False Alarm Rate
65%-70%

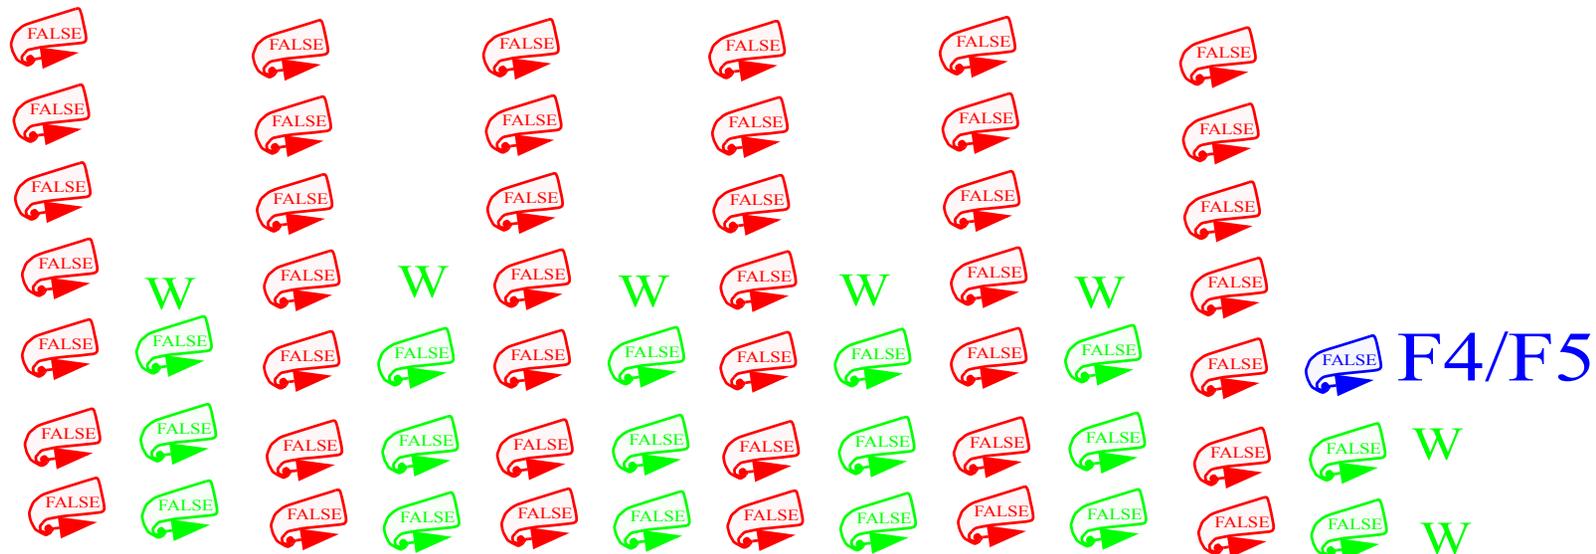

Why run if 2/3 chance false?

We don't know How strong tornadoes will be

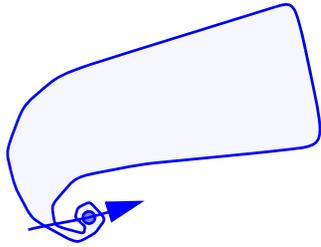

Warnings provide no forecast of intensity

Effective False Alarm Rate for F4/F5 = 98%

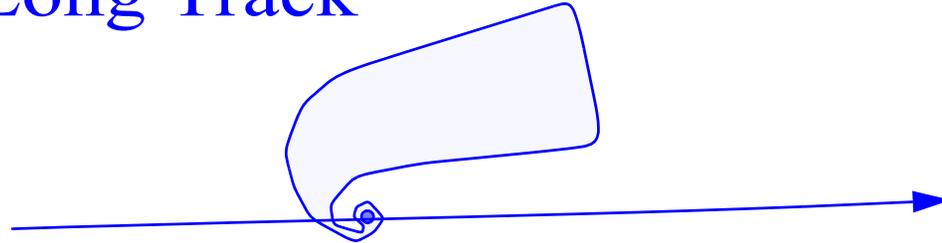

We don't know Length, precise path, evolution

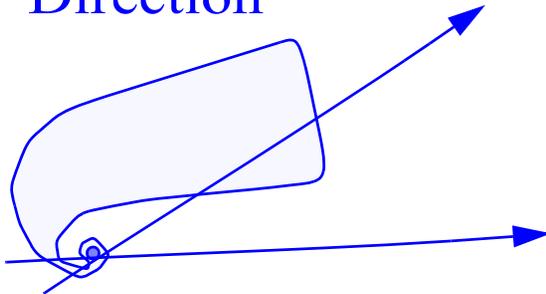

Short Track

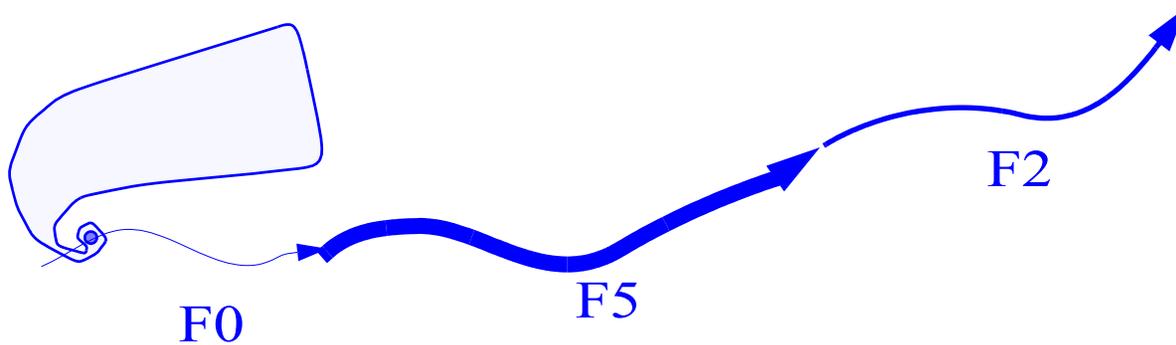

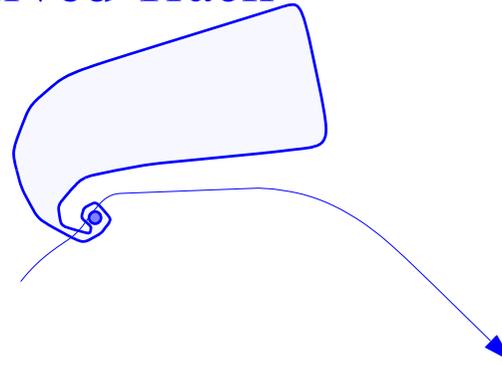

Long Track

Direction

Curved Track

Compare this lack of specifics to

Hurricane Warnings:

track and probabilities

intensity (Cat 1,2,3,4,5)

timing

Blizzard Warnings:

intensity (6-12 inches)

timing

The problem is not with forecasters.

NOAA/NWS/SPC are doing the best they can with available knowledge and observations

NWS skill is nearly maxed out

The problem is with the state of:

- a. Scientific knowledge**
- b. Observations**

Scientific questions about tornadoes

How, when, where they'll form

How strong or long lasting they'll be

How they do damage

How big or strong they really are.

Tornadogenesis:

1. Role of downdrafts and downdraft character
2. Sensitivity of genesis to microphysical and thermodynamic fields
3. Role of small-scale vorticity maxima observed along gust fronts
4. Different genesis modes

Near-Ground Winds:

1. Range of observed tornado characteristics: vertical, radial, asymmetries, multiple vortices, and angular momentum budgets, swirl
2. Relationship between damage and peak wind, wind duration, wind direction

Relationship Between Tornadic Storms and Environment:

1. Favorable and unfavorable storm interactions, mergers
2. Effects of environmental heterogeneity

Why don't scientists know these things?

Good enough observations do not yet exist

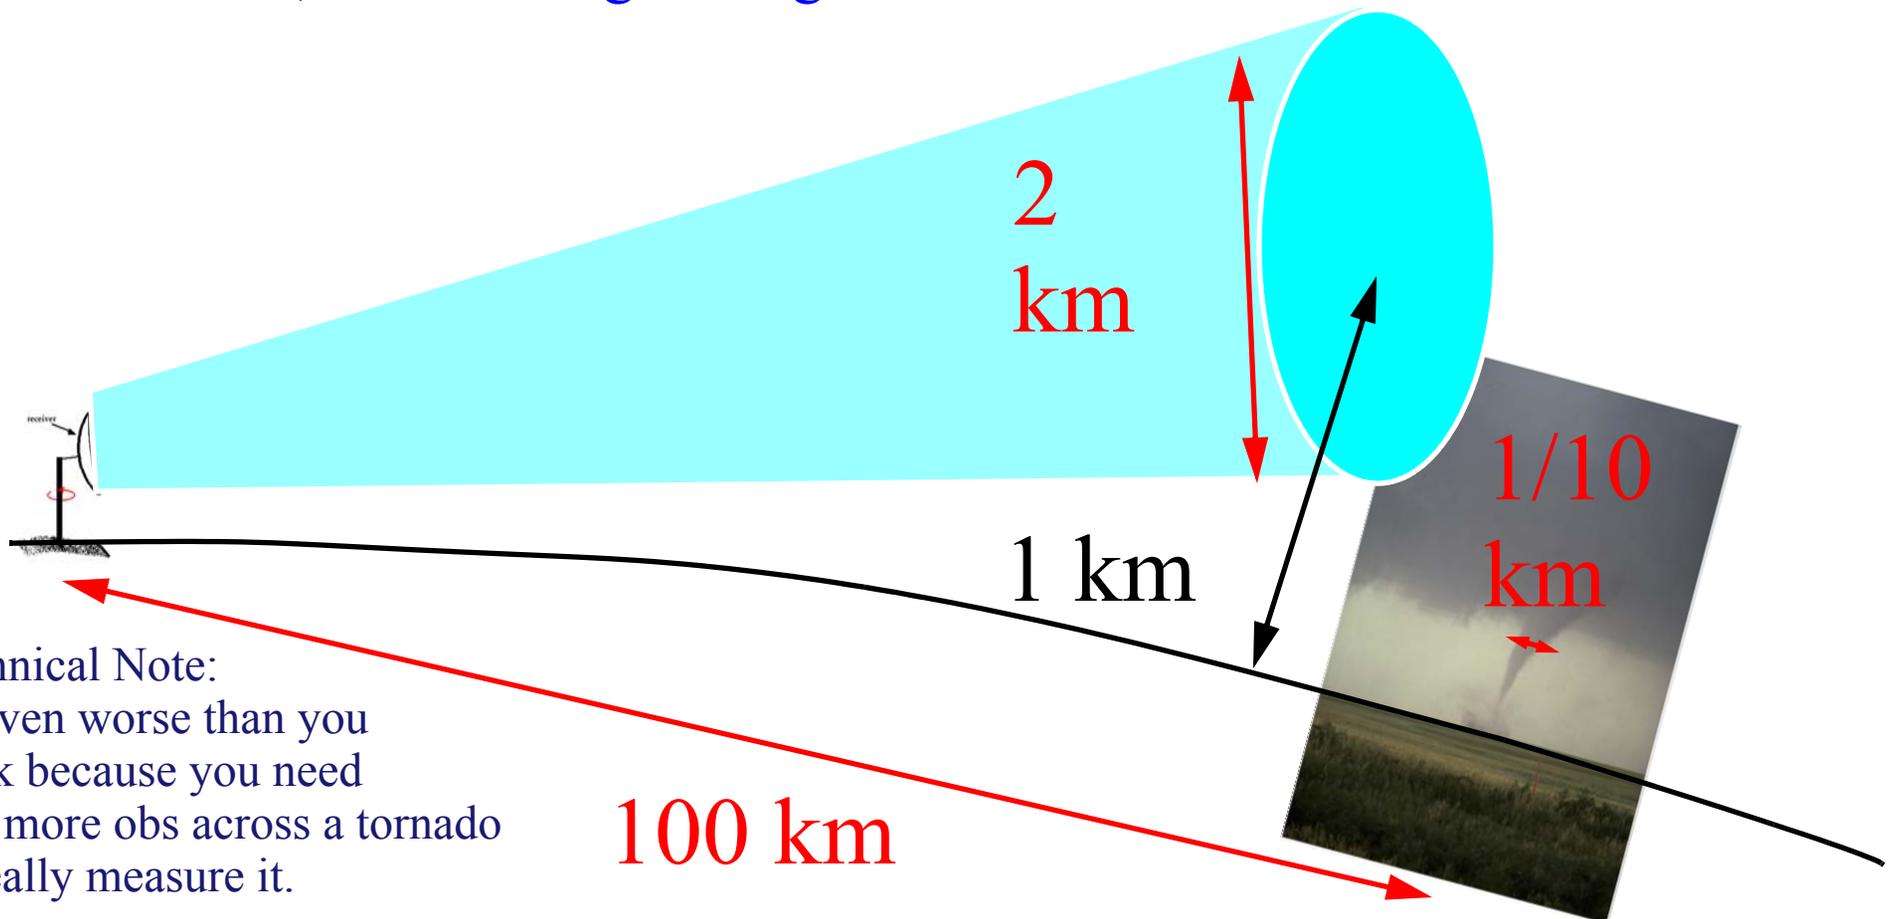

Radars have revolutionized warnings

But...

Normal Radars Can't See Tornadoes

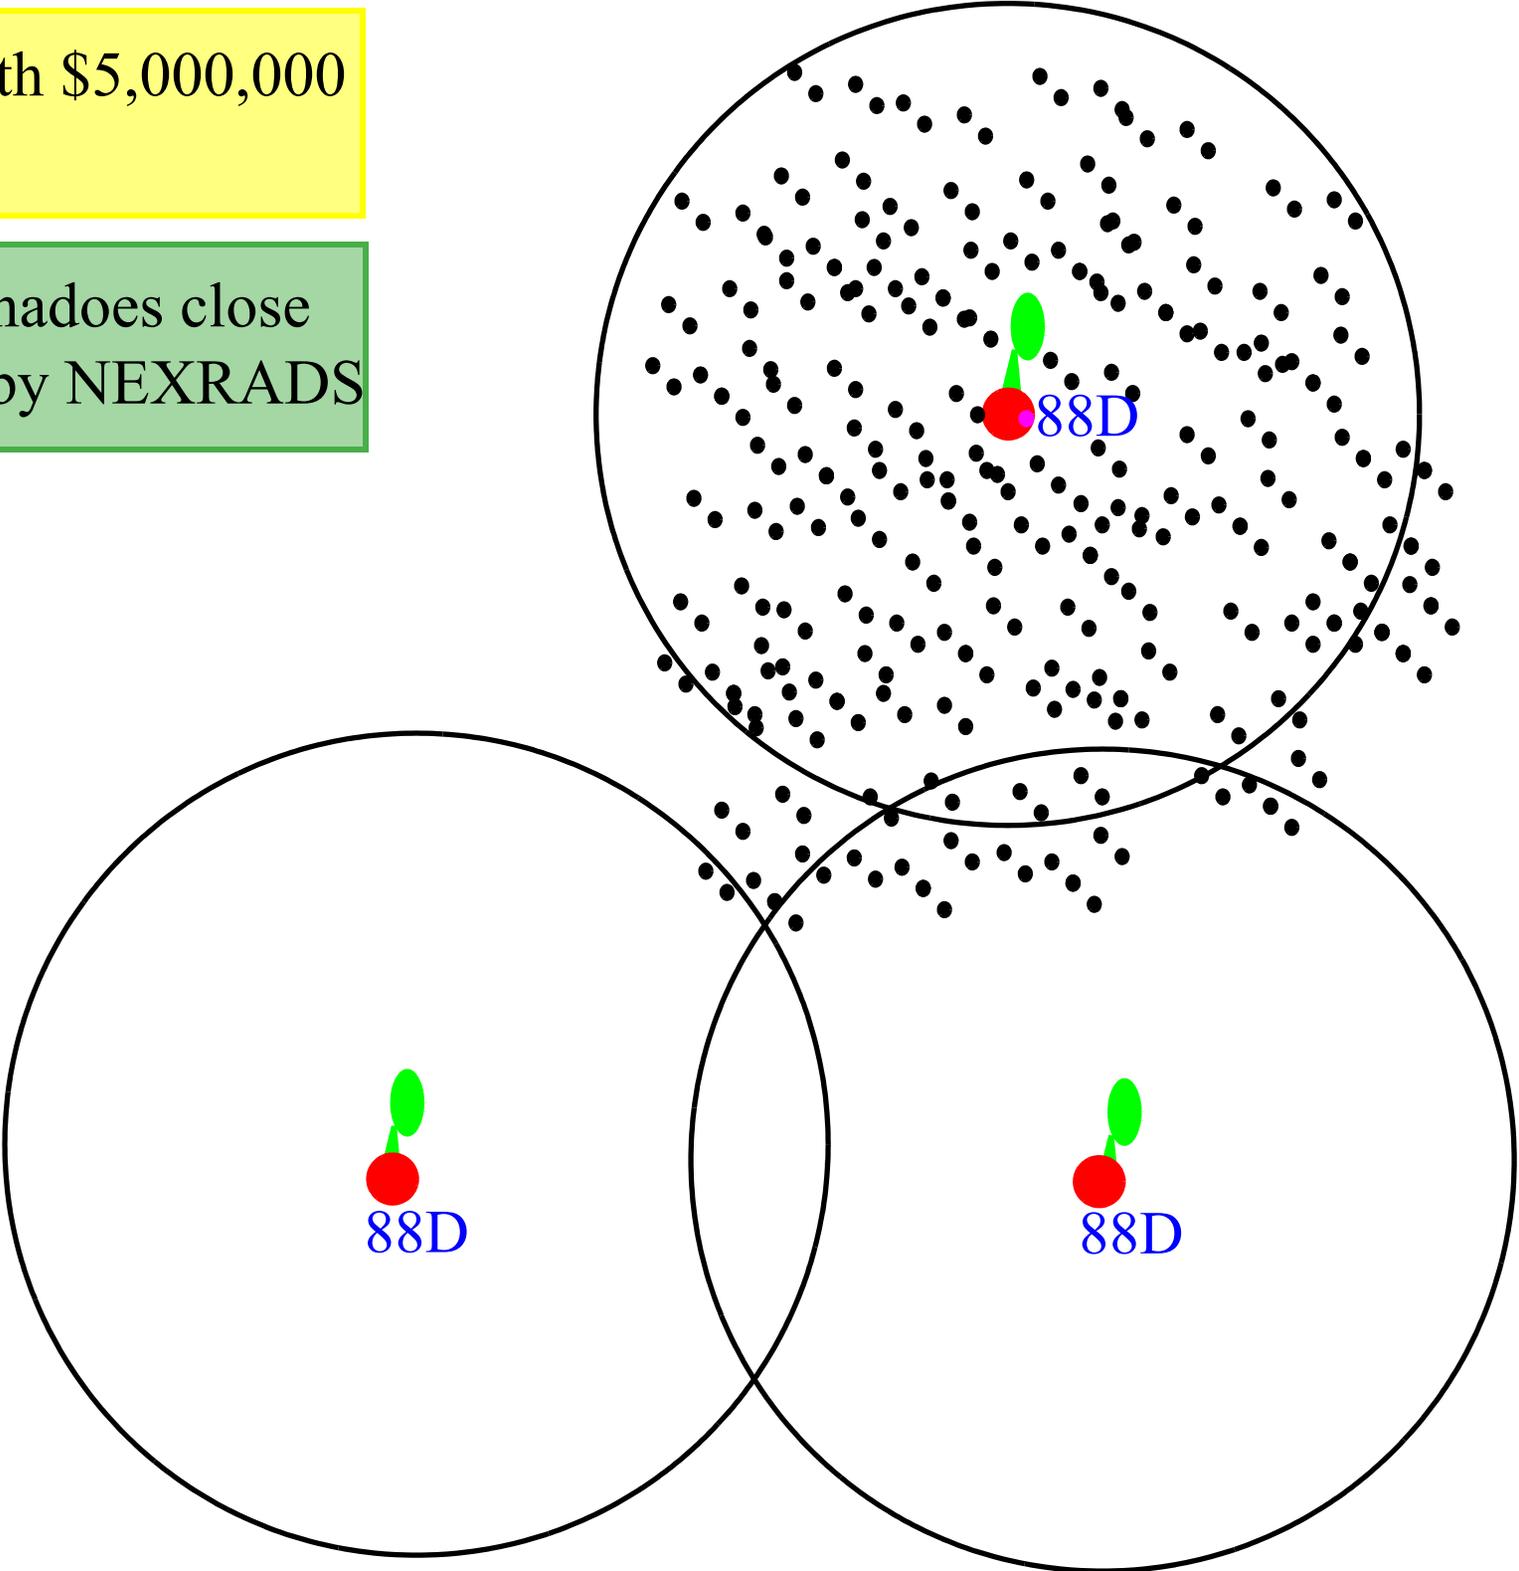

Radar beams spread with distance and are much bigger than tornado

Earth curves, but beams go straight and radar can't see near the surface

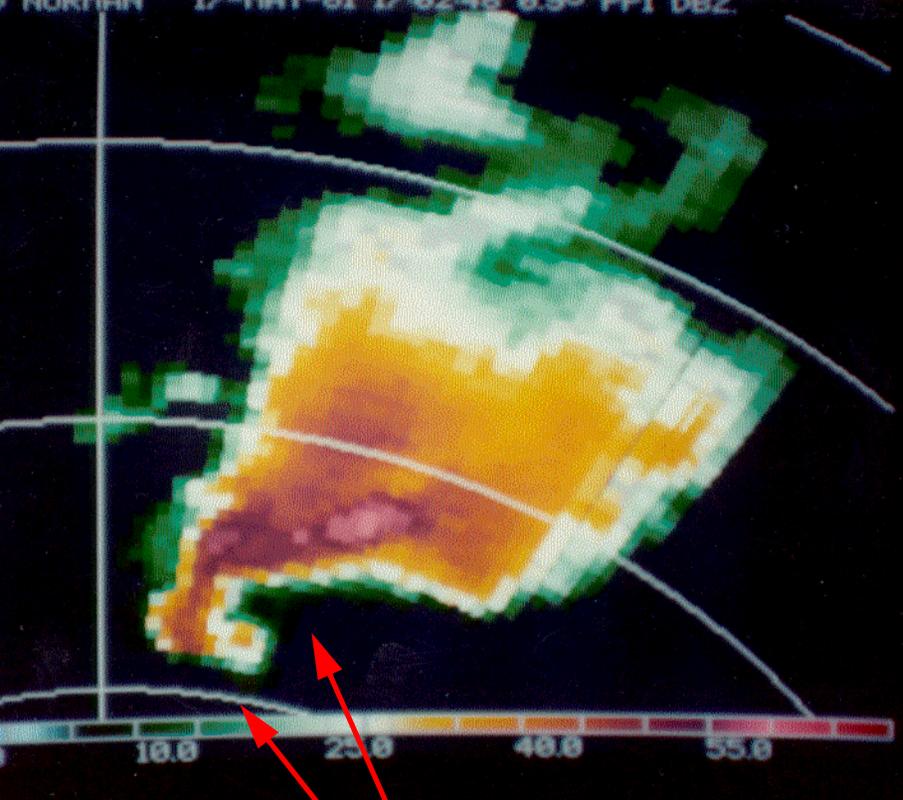

USA is covered with \$5,000,000 NEXRADS

Only 1/1000 of tornadoes close enough to be seen by NEXRADS

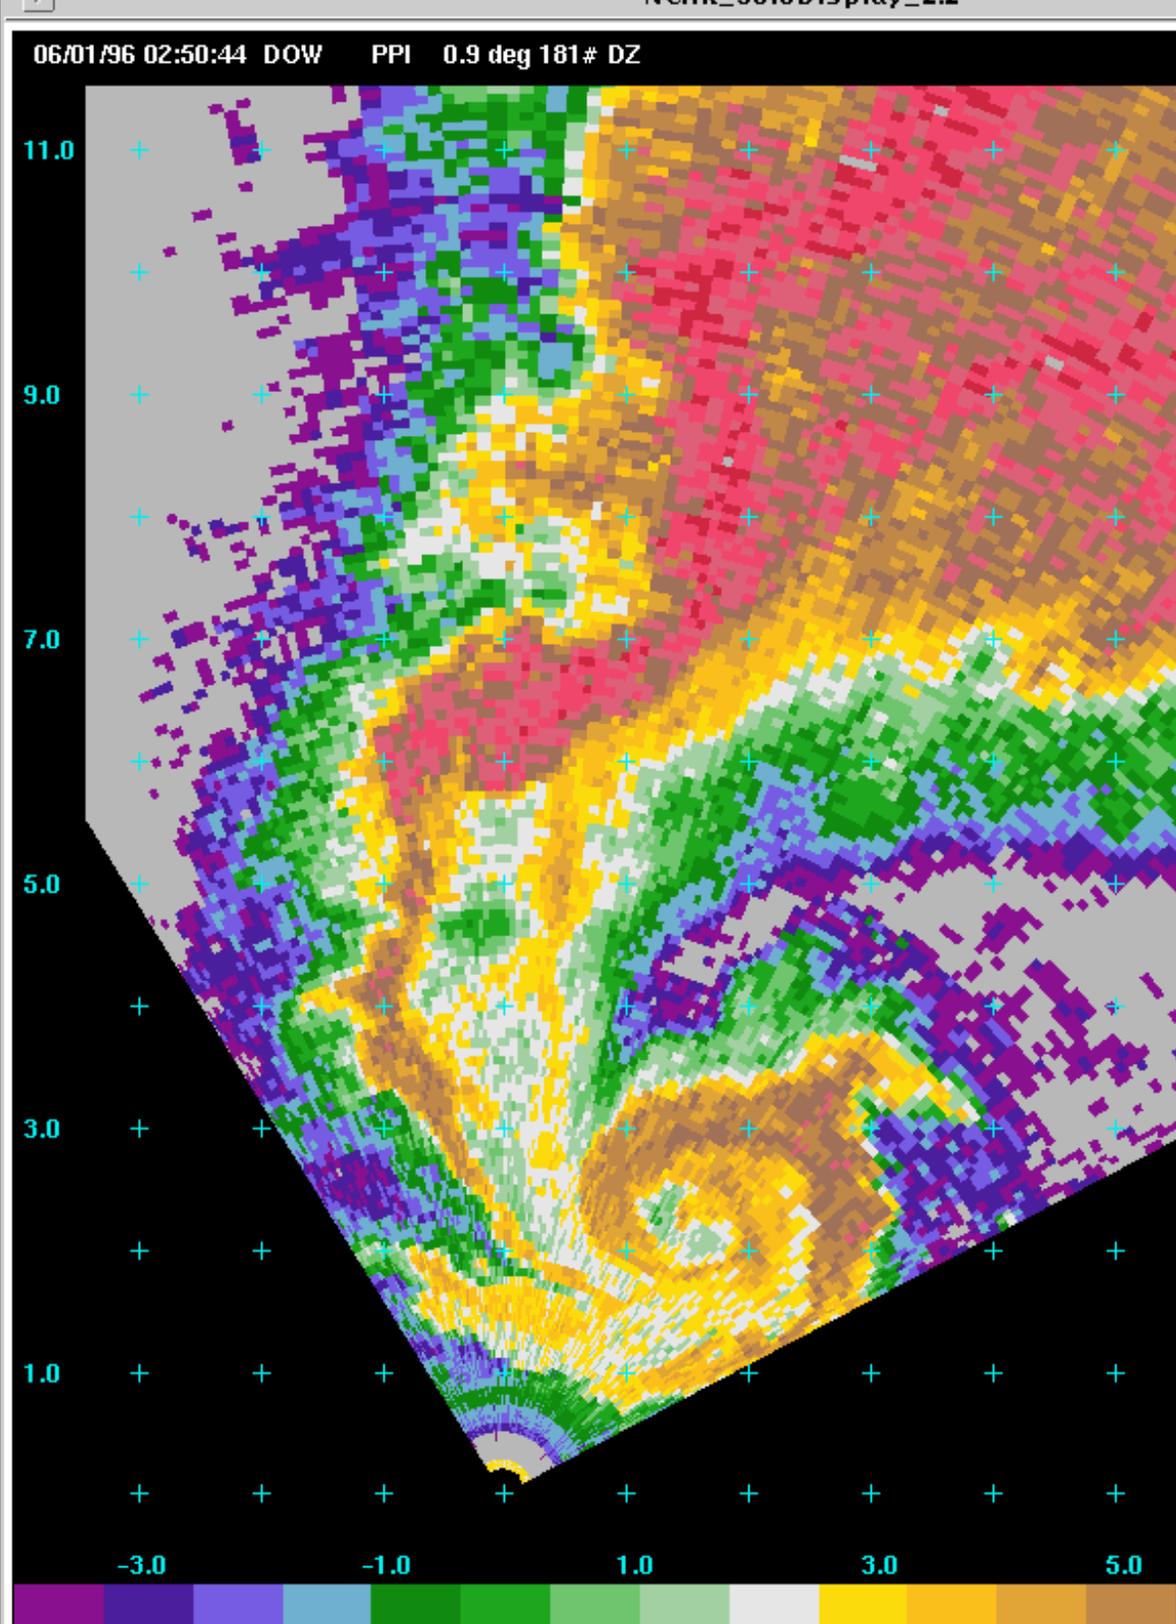

Solution: Take Radars to the Tornadoes

Get up close
detail: 50x50x20 better
= 50,000x smaller
10x50 times faster

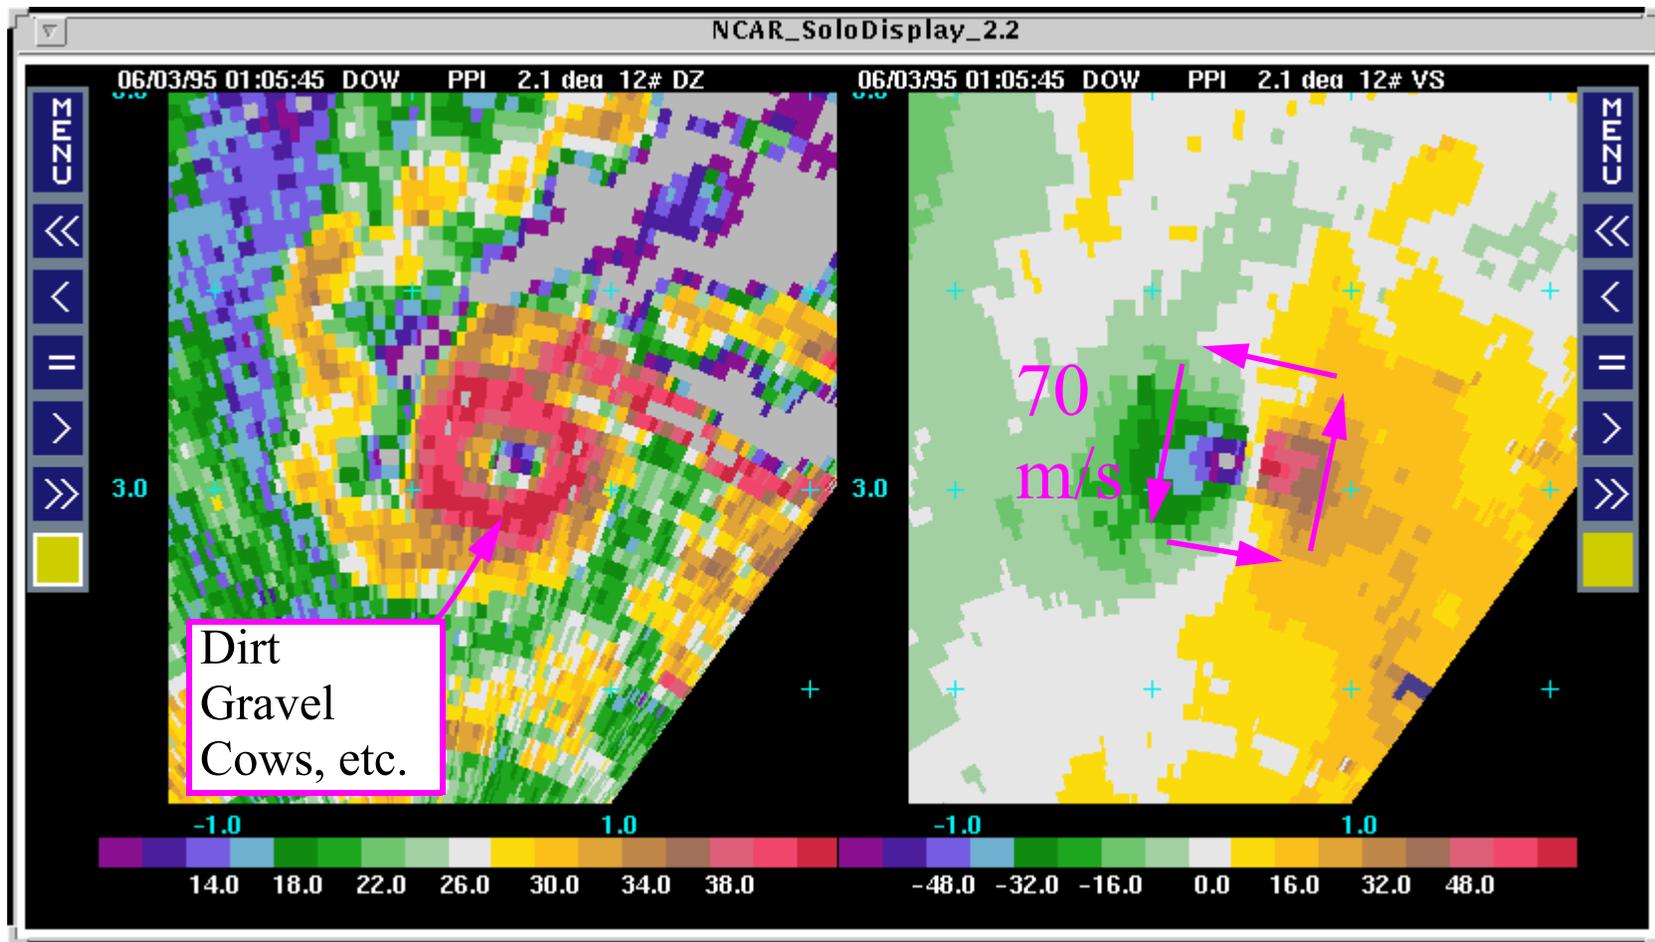

Three Observational Pillars to Answer Questions about Tornadoes

Small Scale

Fast Updates

Low to the Ground

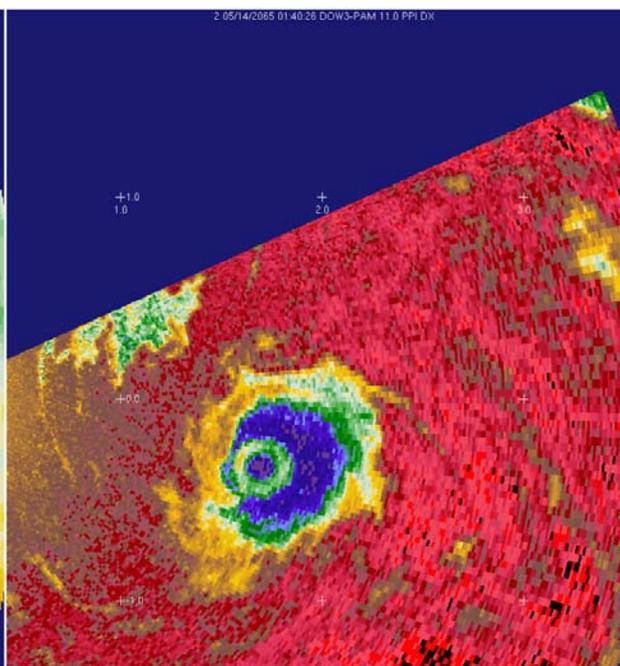

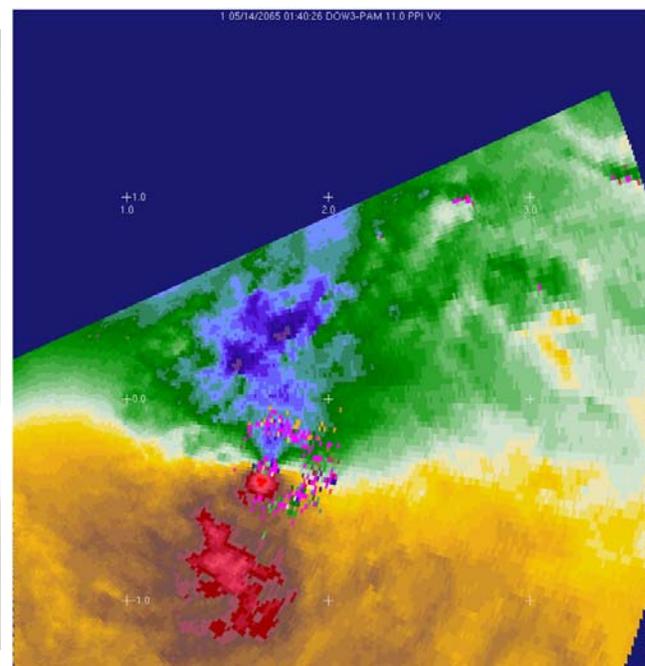

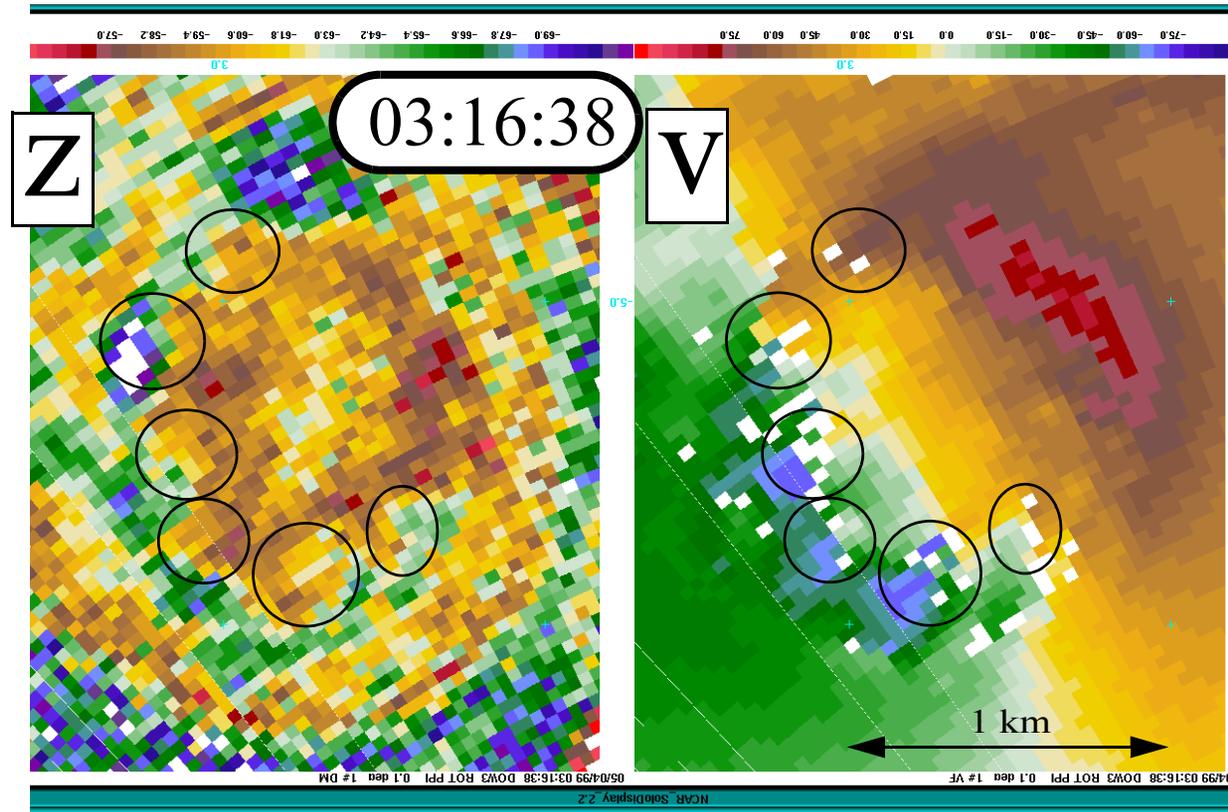

**Reflectivity/Power
sees debris/rain**

**Doppler velocity
sees towards/away
motion of debris/rain**

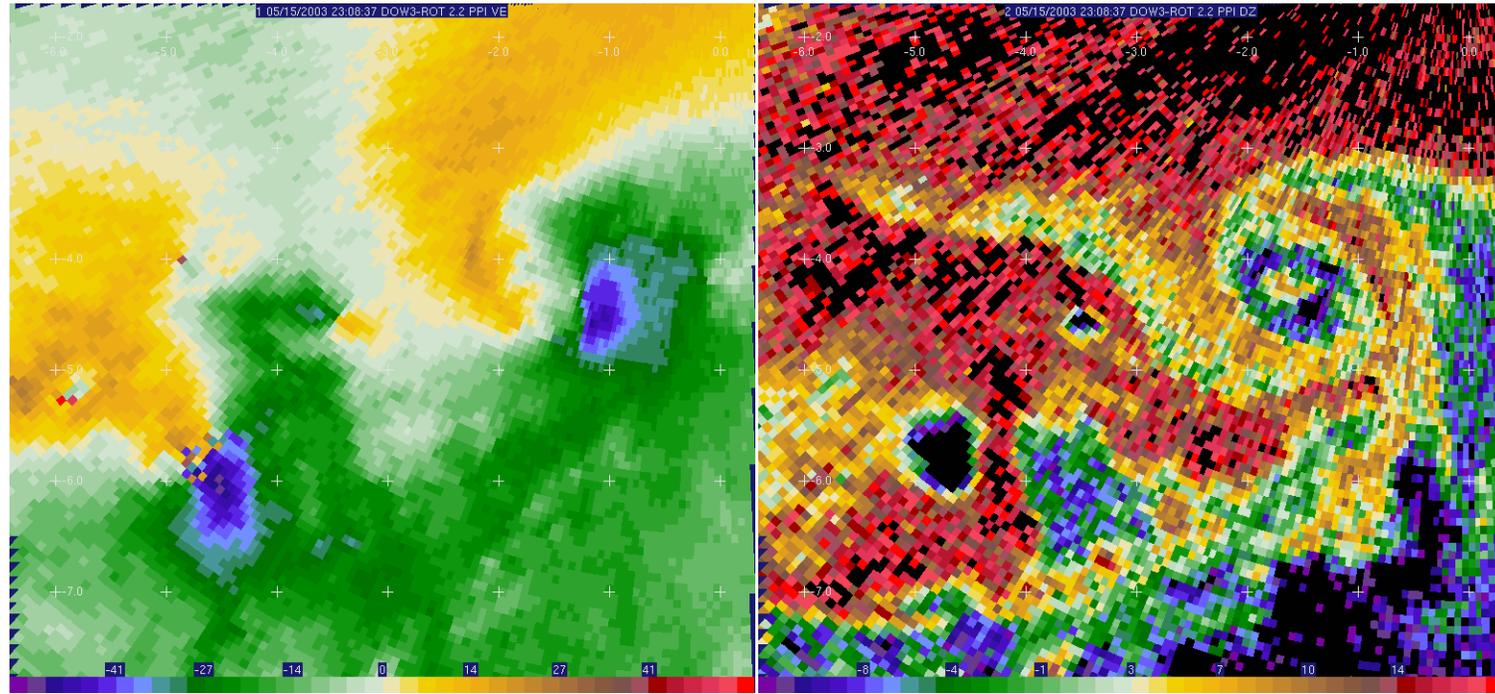

The basics of DOW tornado observations

Multiple Vortices Complex Structure

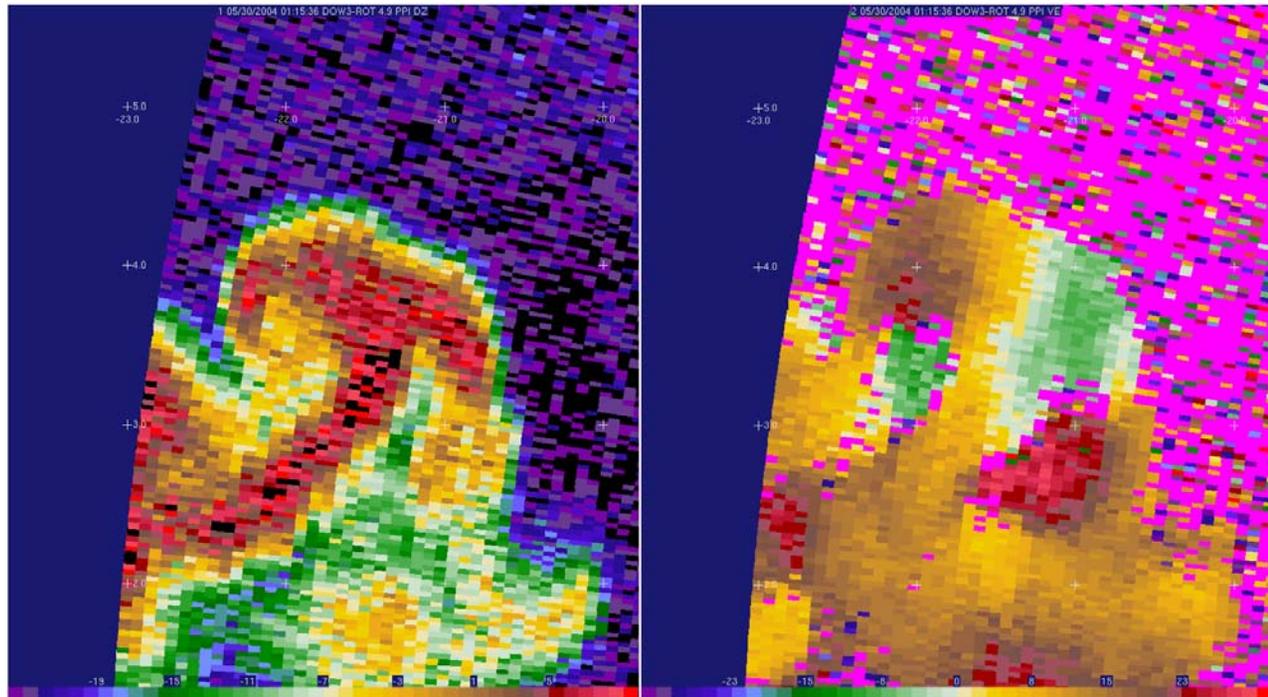

**DOWs Observed
100 Tornadoes
1995-2005**

Double Tornadoes

Backwards Tornadoes (anticyclonic)

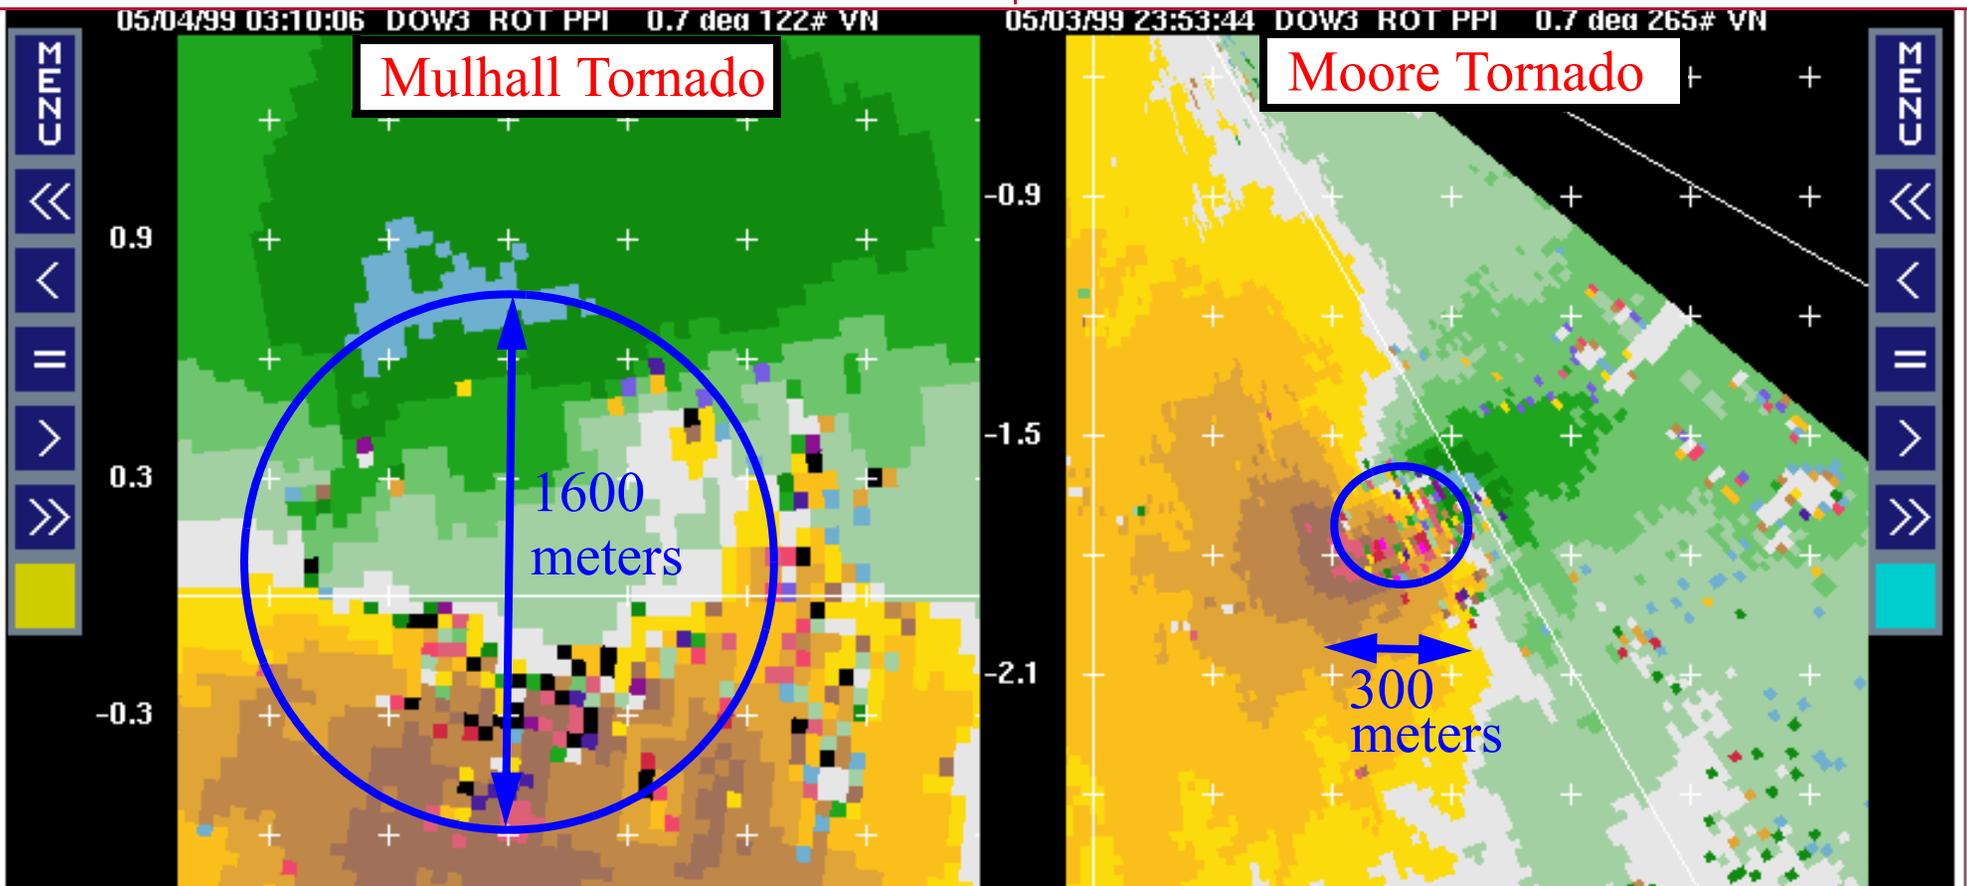

How Big are Tornadoes? (no one really knows)

**Unknown Mulhall
Tornado...4x larger**

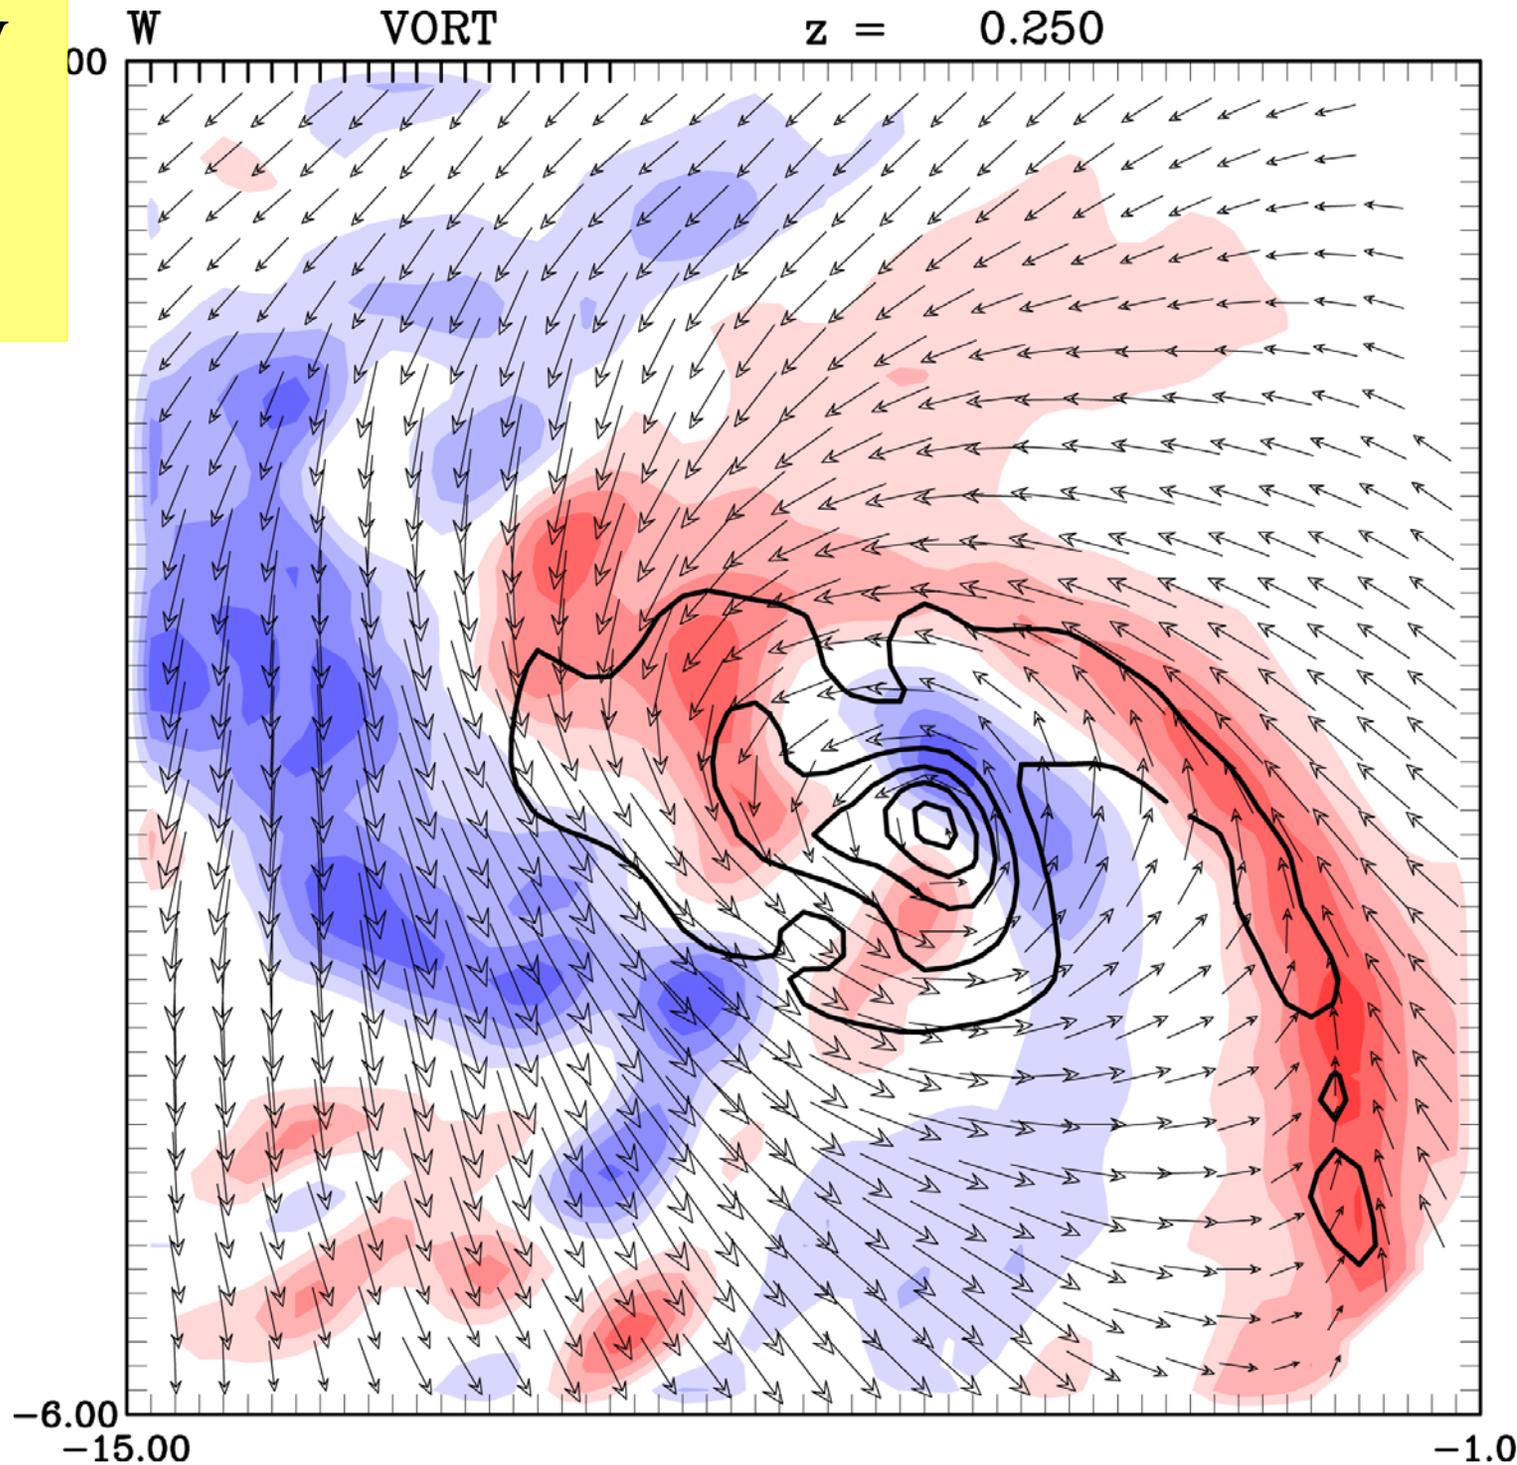

Famous OKC Tornado

**What if this had crossed over
OKC, ORD, NYC, or DC?**

**How do they
form, die,
strengthen?**

**Wind
Vectors
Resolve
Sources
of
Rotation**

How strong are the winds in tornadoes?

We don't know

Until DOWs, only method was to look at damage

The Fujita-Scale

Very approximate

Only works when tornadoes cross towns

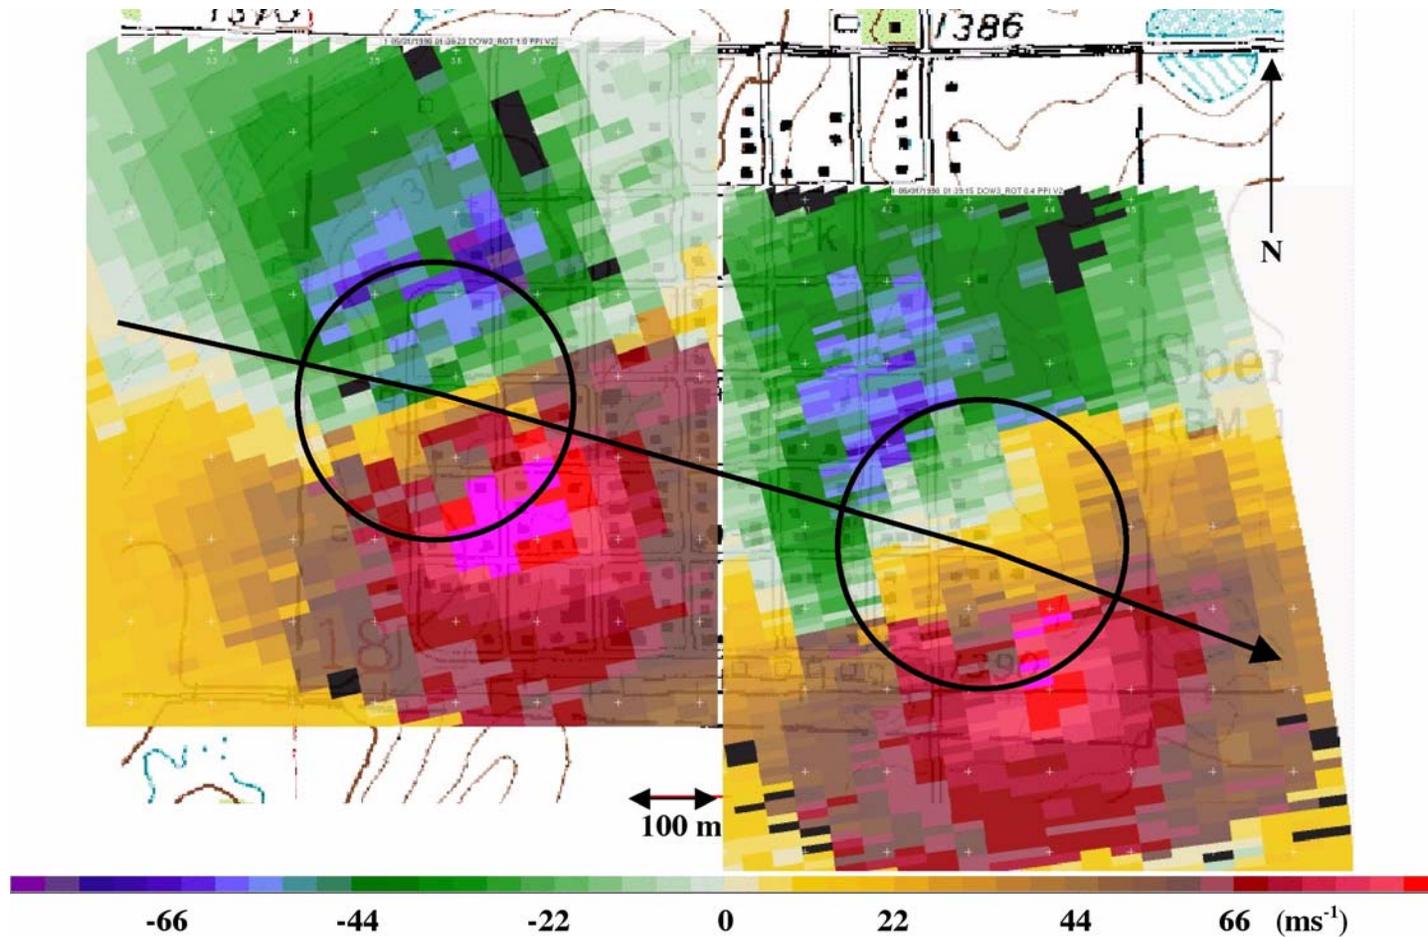

Spencer, South Dakota Tornado, 31 May 1998 Damage and Winds Measured

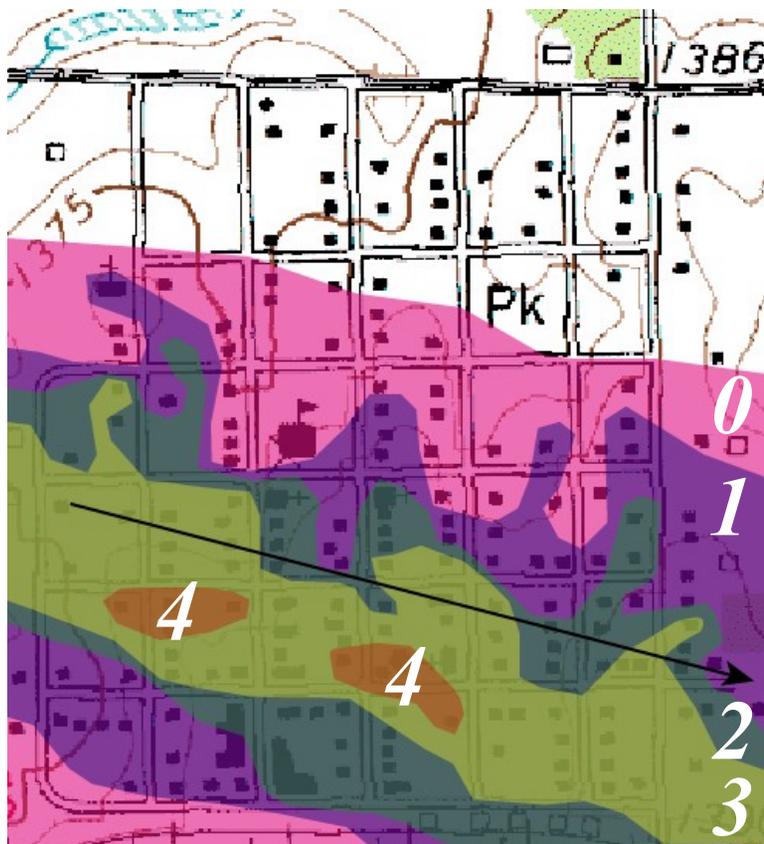

DOW Measured Winds over *every* house

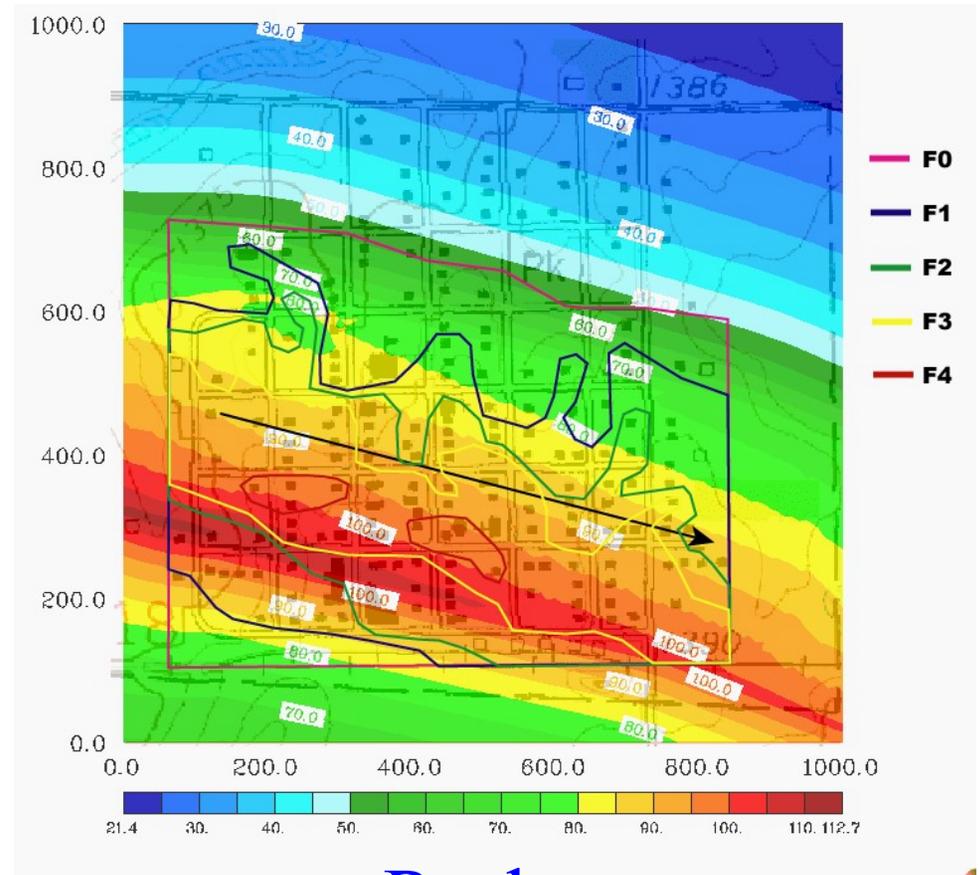

Damage vs Winds

Damage Survey F-scale

Peak
1/4 mile
"F" wind

Three Observational Pillars

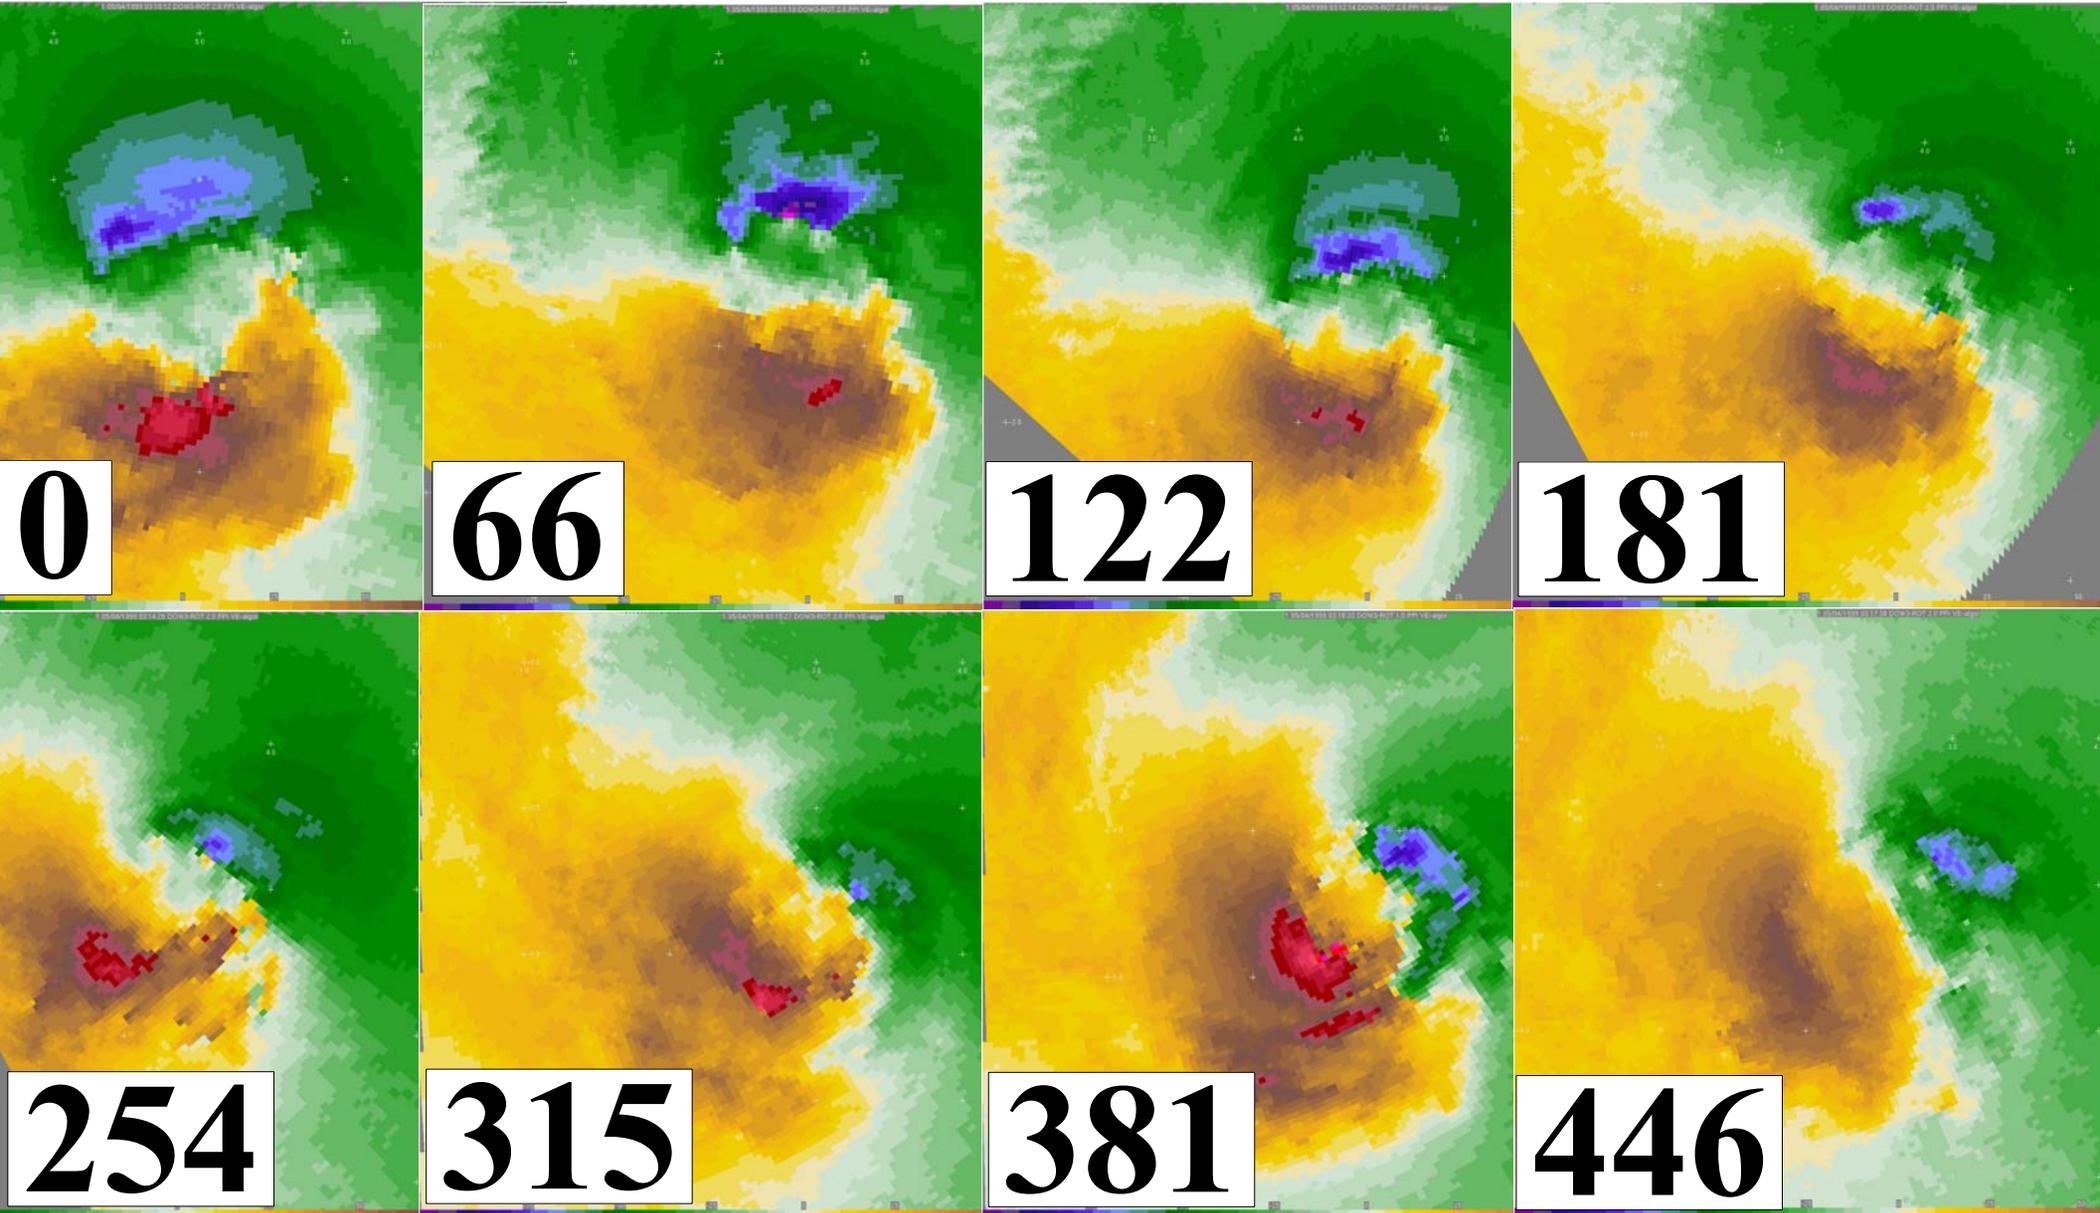

Small Scale

Fast Scanning

Low to the Ground

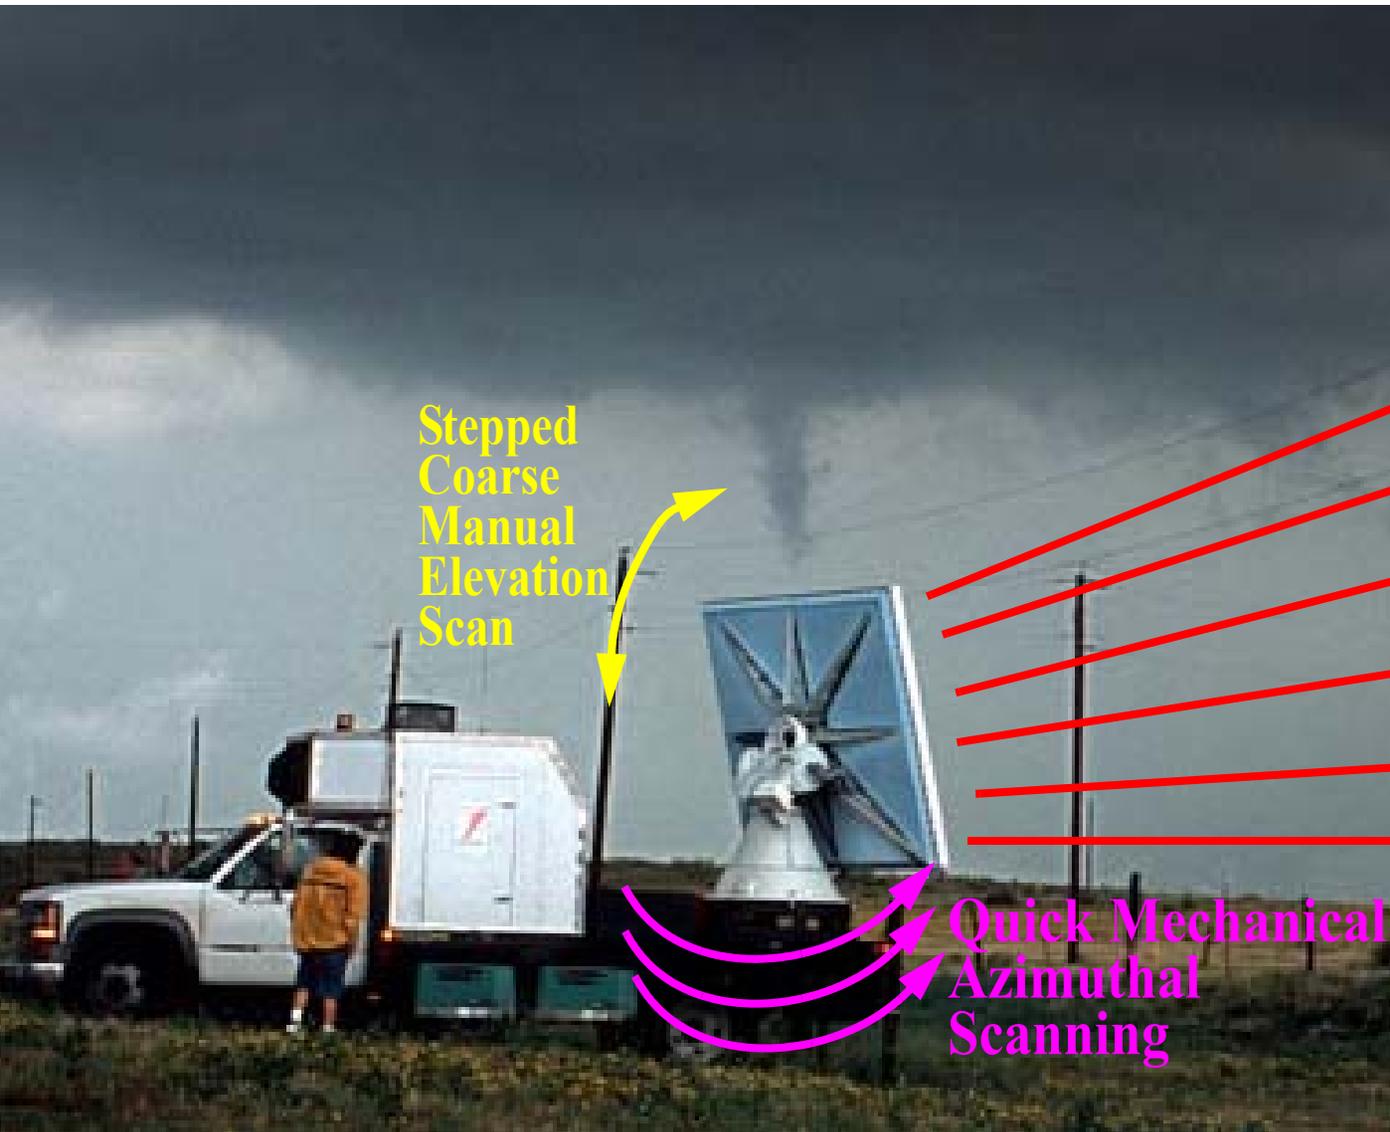

Tornadoes Evolve Very Quickly

Evolution can't be seen with 5 min 88D, 1-2 min CASA, even 50 s DOW

6 Beam Radar just built by CSWR with NSF support

3D volumes in 10 seconds

Current
Low Dispersion
Feed

9680 MHz 5.0°

9604 MHz 4.0°

9528 MHz 3.0°

9452 MHz 2.0°

9376 MHz 1.0°

9300 MHz 0.0°

Azimuthal Scanning up to 60°/s
for 6-7 s surveys and 4 s sectors

Three Observational Pillars

Small Scale

Fast Scanning

Low to the Ground

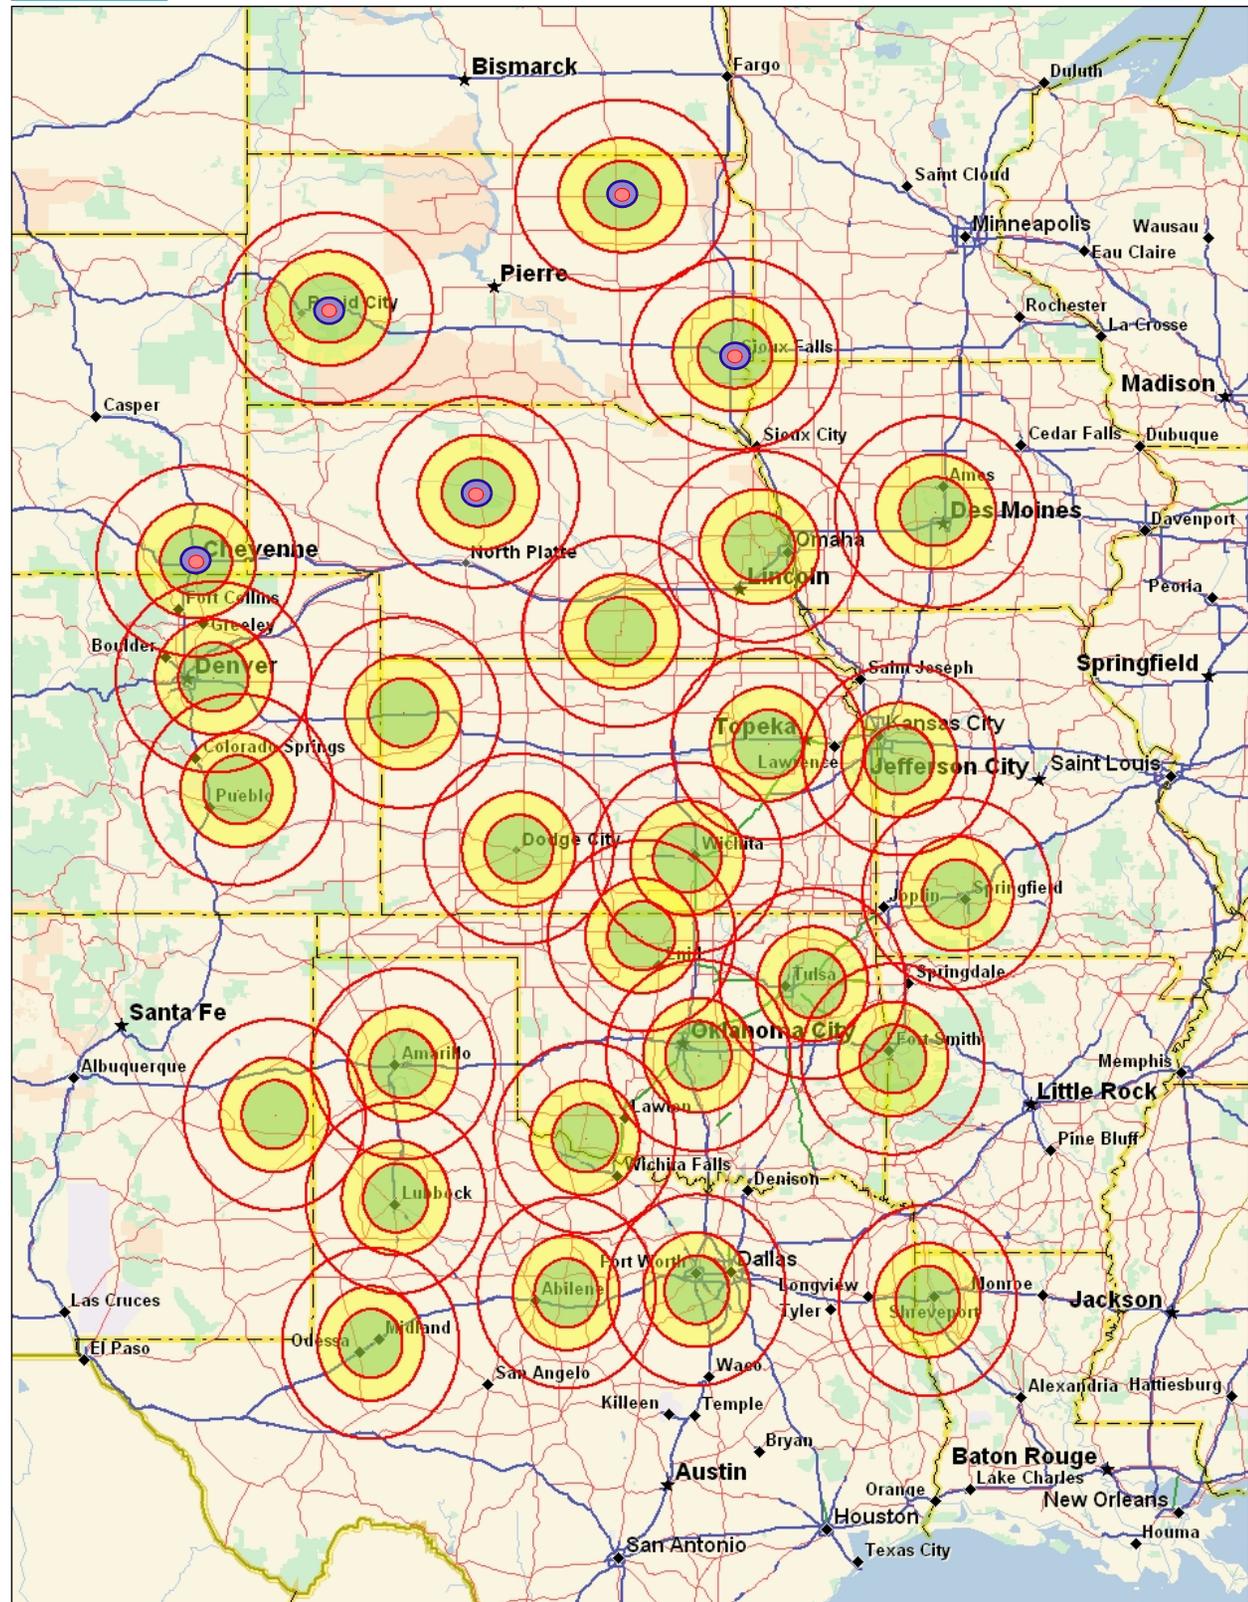

The other “cone of silence”

88D Network

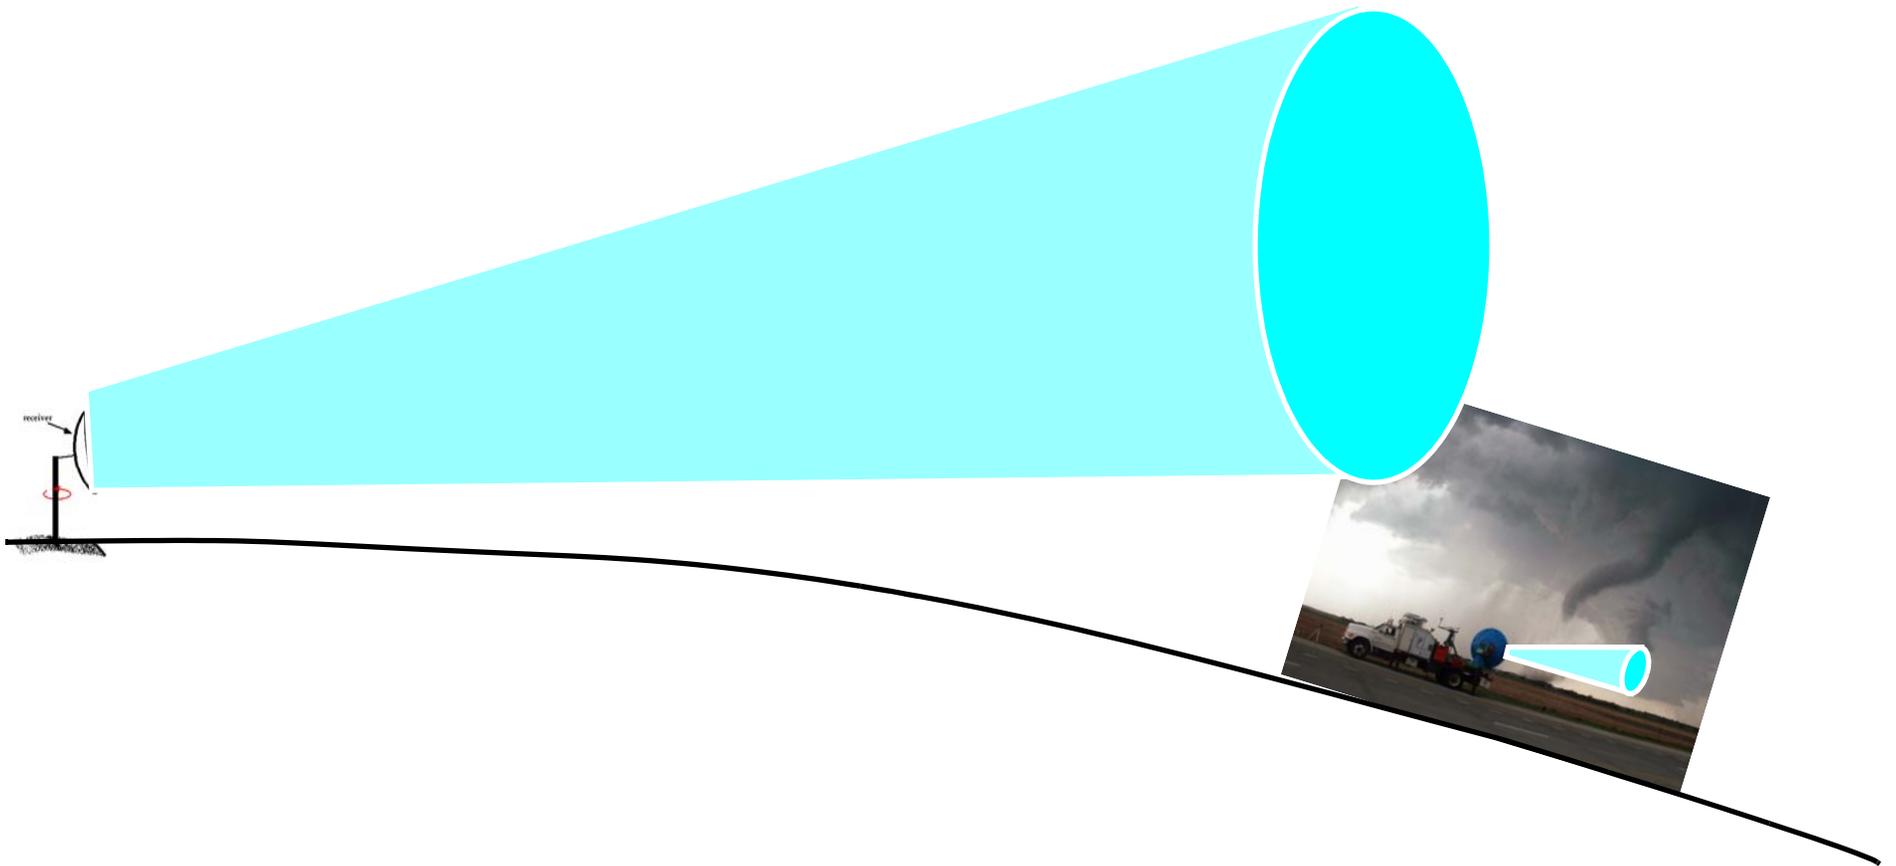

- 65% invisible < 1000 m
- 88% invisible < 500 m
- 97% invisible < 250 m
- 99.5% invisible < 100 m
- 99.9% invisible < 50 m

Even with CASA

- 50% invisible < 240 m
 - 92% invisible < 100 m
 - 98% invisible < 50 m
- (assumes 1° elev of center of CASA beam)

Up Close Radars Can See Low to Ground

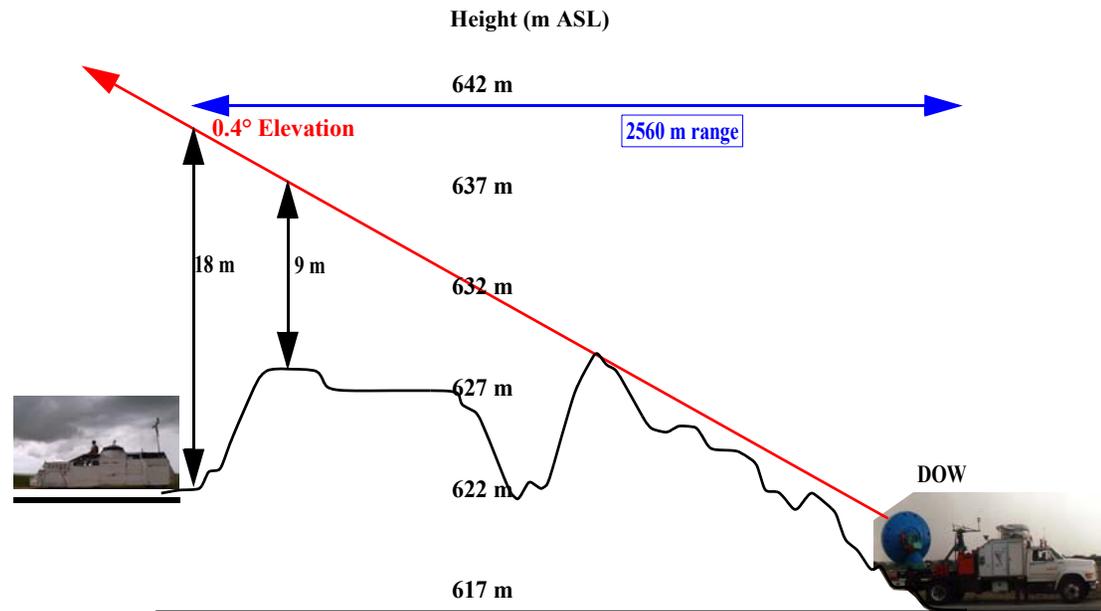

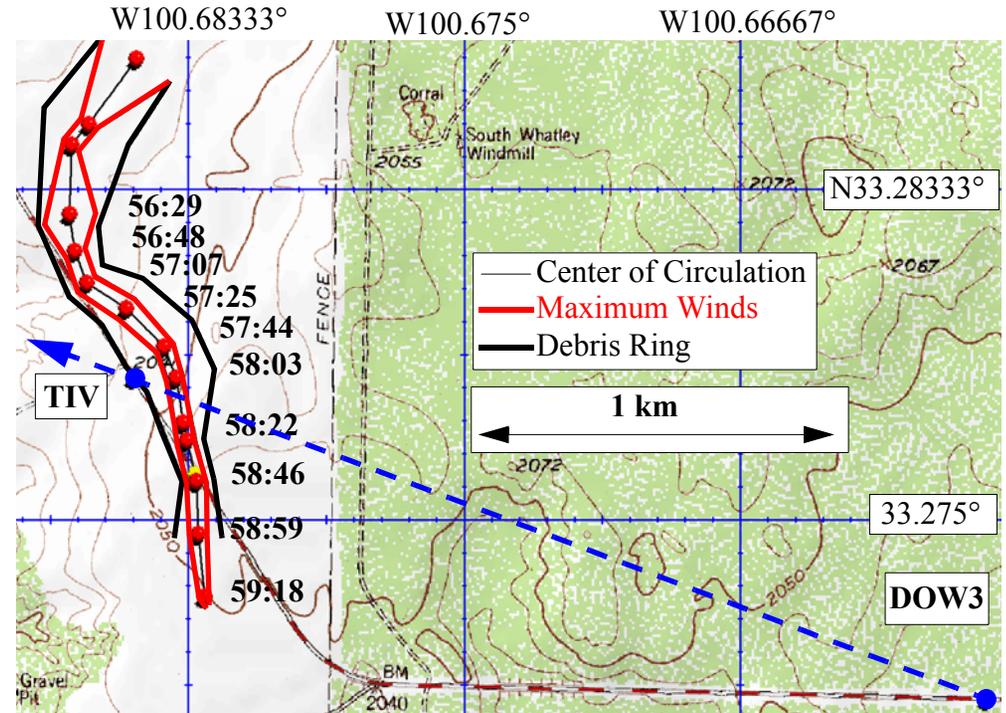

Combine DOW and In-Situ Observations for Observations Right At Ground

Tornado Passes Over “Tank”

DOW Scans Overhead

Future Technology Alternatives

	Existing WSR-88D	Dense Network CASA	Stationary Phased-Array	DOWs Mbl Balloons Mbl Profilers
Small Scale	No	Fair	No	Yes
Fast Scan	No	Fair	Yes	Yes
Low	No	Fair	No	Yes
# Needed To See All Storms	100	5000	100	100
Cost per	5-10M\$	100k\$	20M\$	200k\$
Cost network	exists	500M\$	2B\$	20M\$

A “few” DOWs cannot observe many tornadoes: Research Only

1000 tornadoes per year

20 observed by DOWs each year

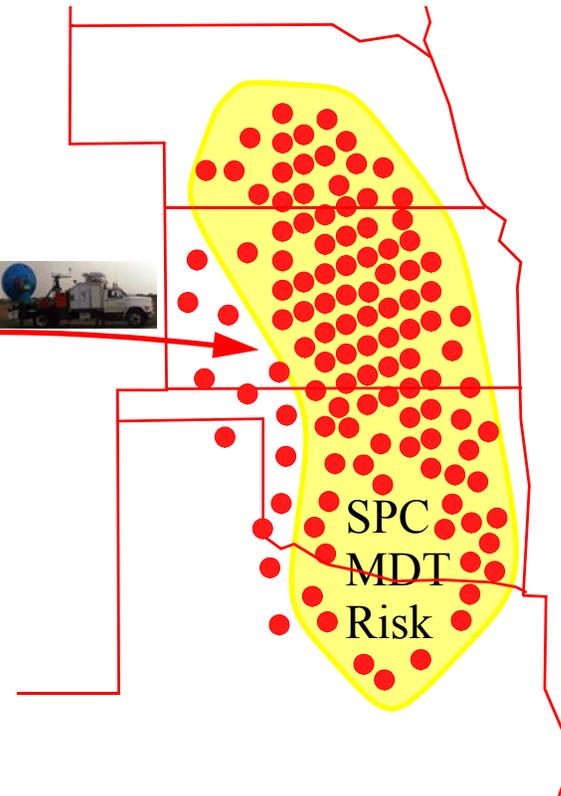

98% not observed by Research DOWs

**Targeted
Operational
Radar
Network**

Each Day

Dense DOW Array
Pre-Deployed
to SPC Risk Area

+balloons
+profilers

**Small
Fast
Low**

Affordable

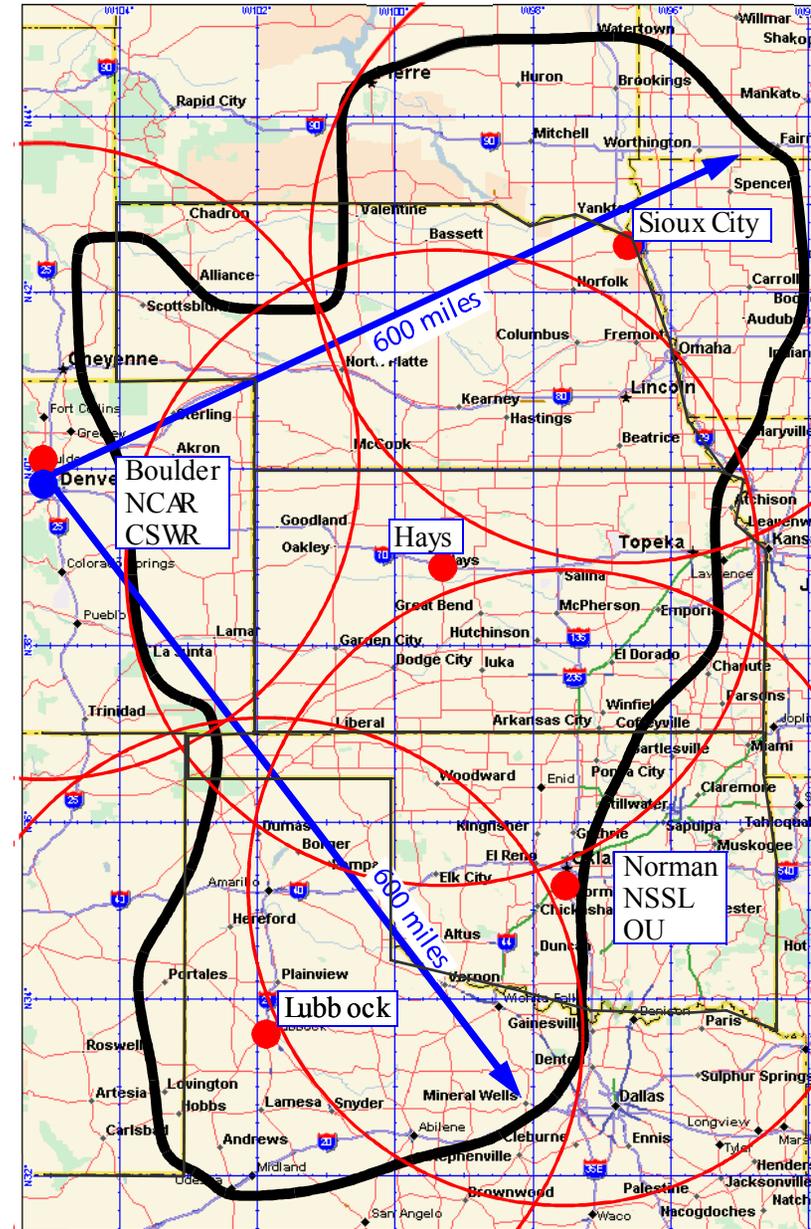

**The Future is Adaptable Targeted Observations
(Hurricane Forecasters Already There)**

Adaptable Observation Experiment

VORTEX 2

Currently planned for 2008-9
Decision by NSF expected: June

Aircraft, DOWs, UAV's, cars

Adaptable Observations

Hurricanes Mapping intense winds
+neighborhood variability

Fires Mapping hot spots
Forecasting wind shifts

Italy, Alaska, California, Germany...

Juneau

Homeland Security: Particle/Gas Releases

Fire Suppression: Water Drops

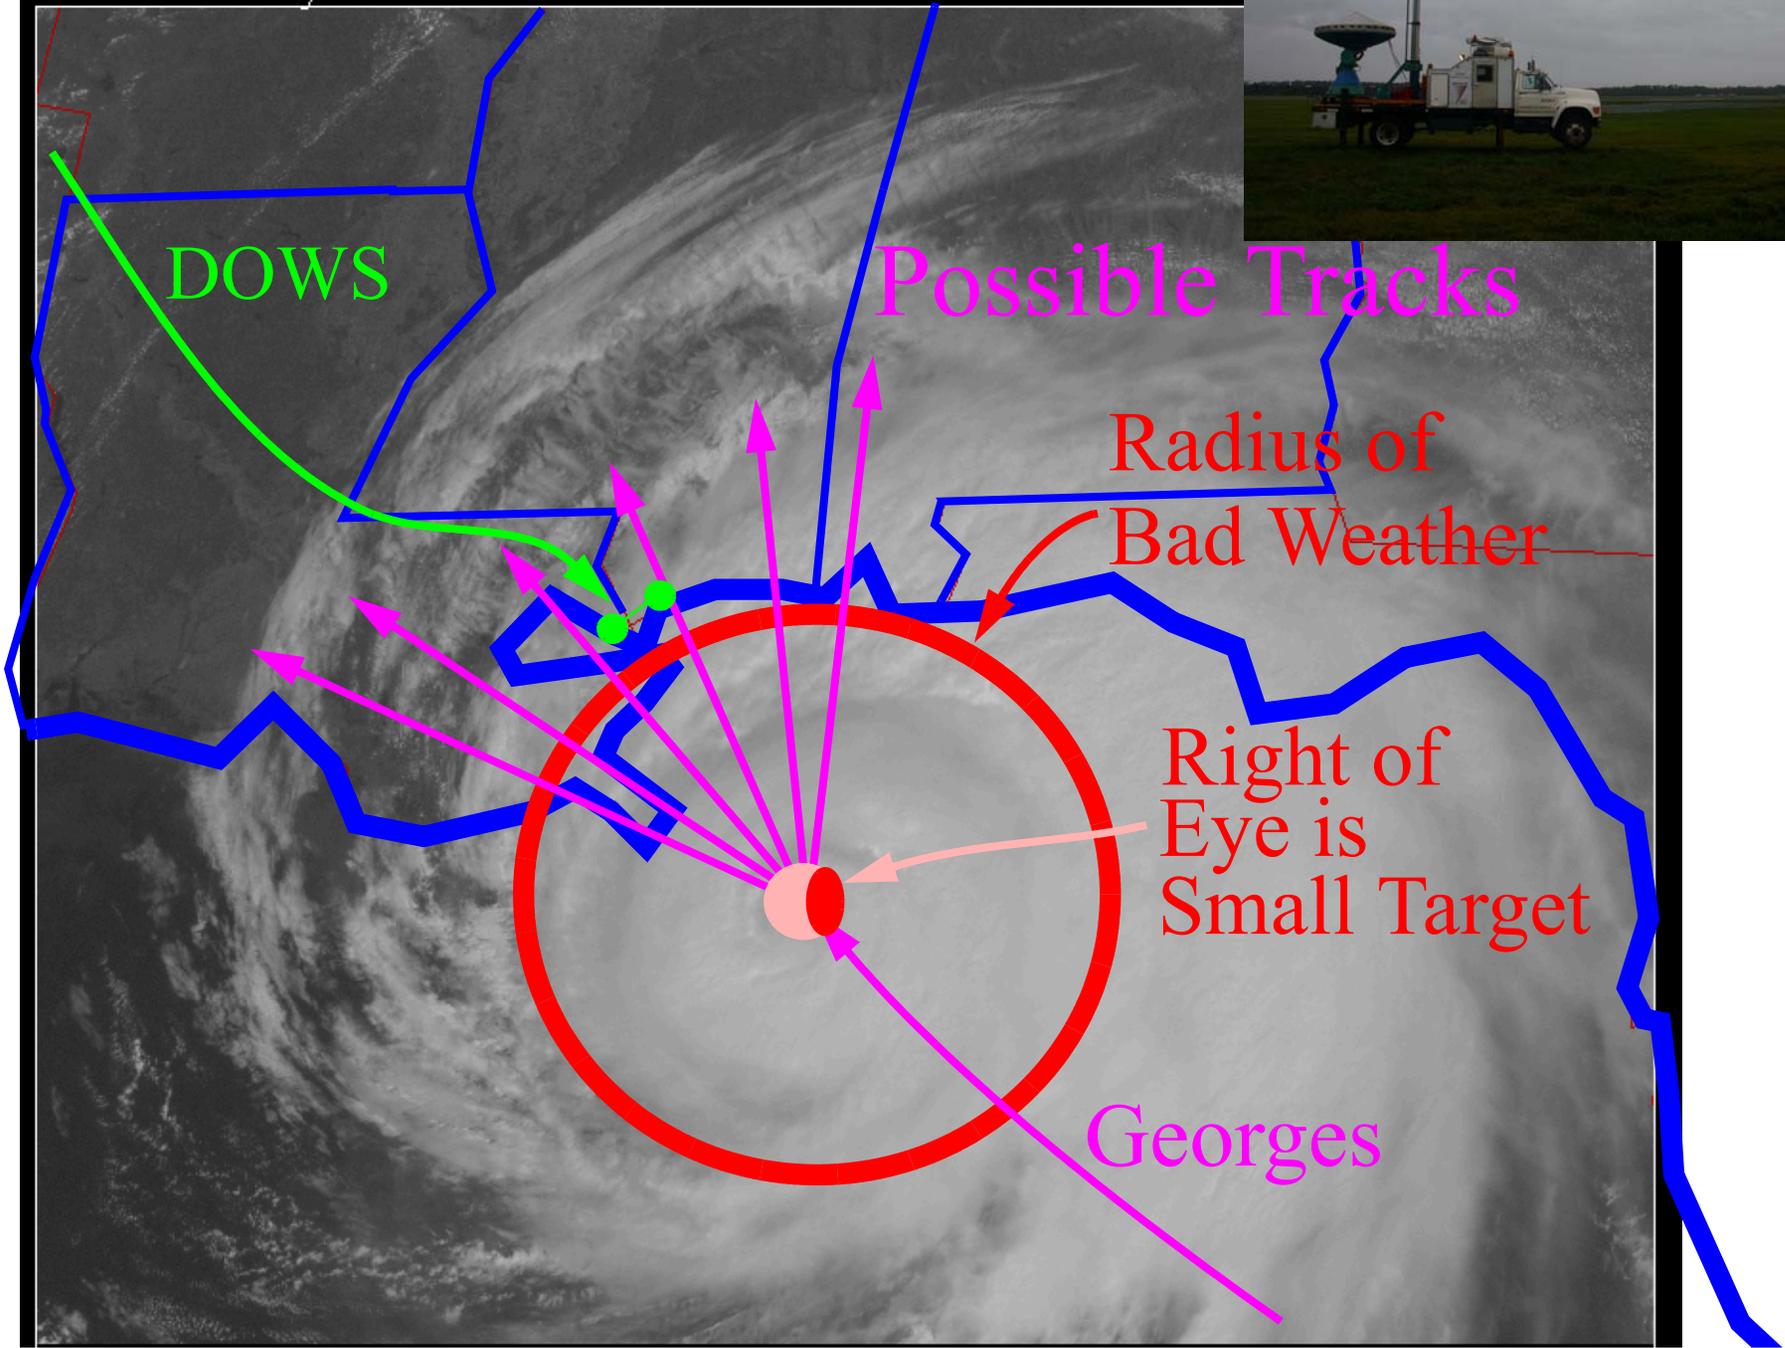

Air Traffic Safety: Turbulence

Chico

(We're

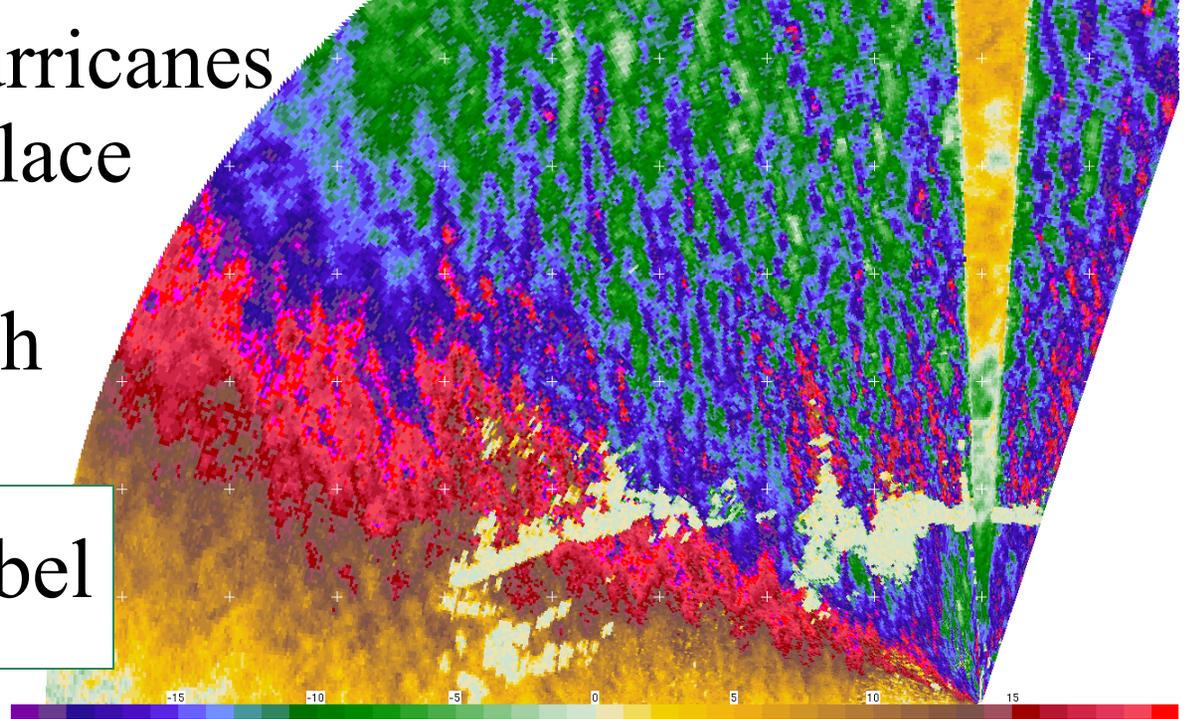

Floater Image

We have to pick our spot before red circle comes onshore

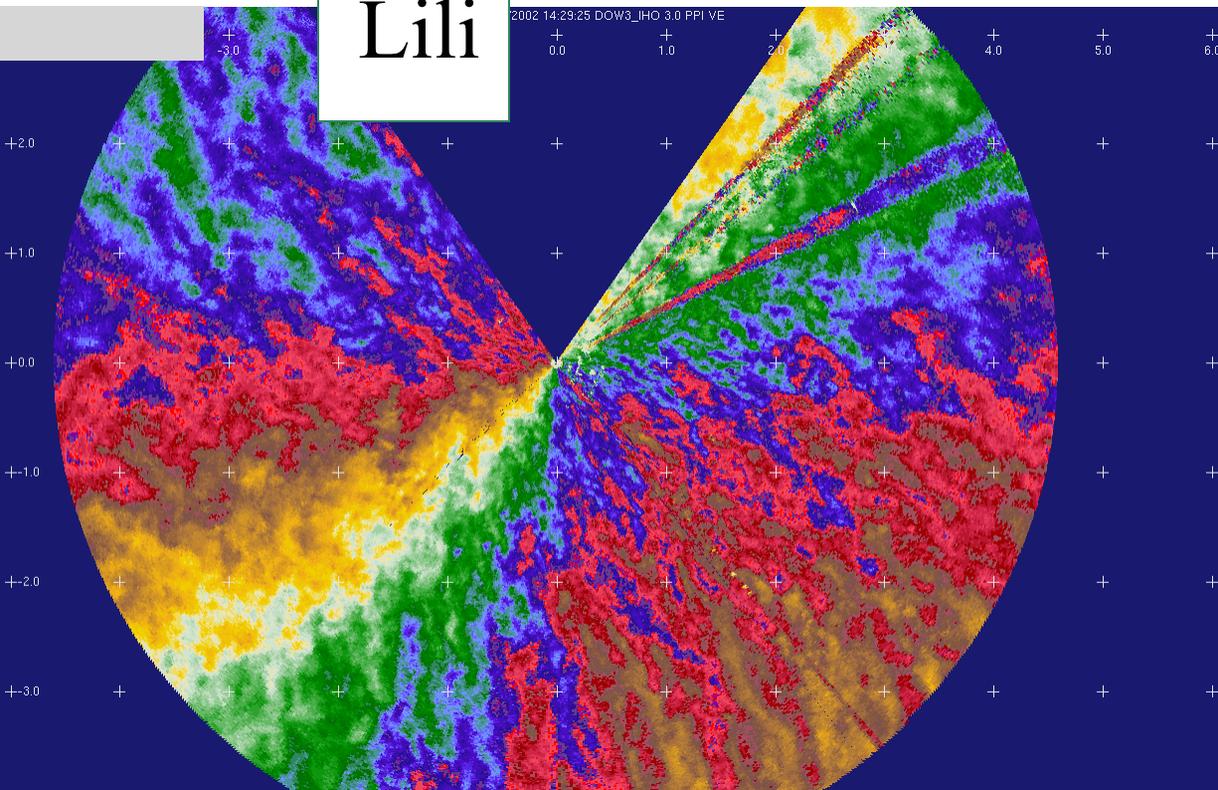

Winds in Landfalling Hurricanes are very different from place to place. Some areas are experiencing 120 mph while others just 80 mph

Potential Urban Impacts of Violent Tornadoes

**What if a violent, long-track tornado hit
Chicago, or New York, or Atlanta, or Washington?**

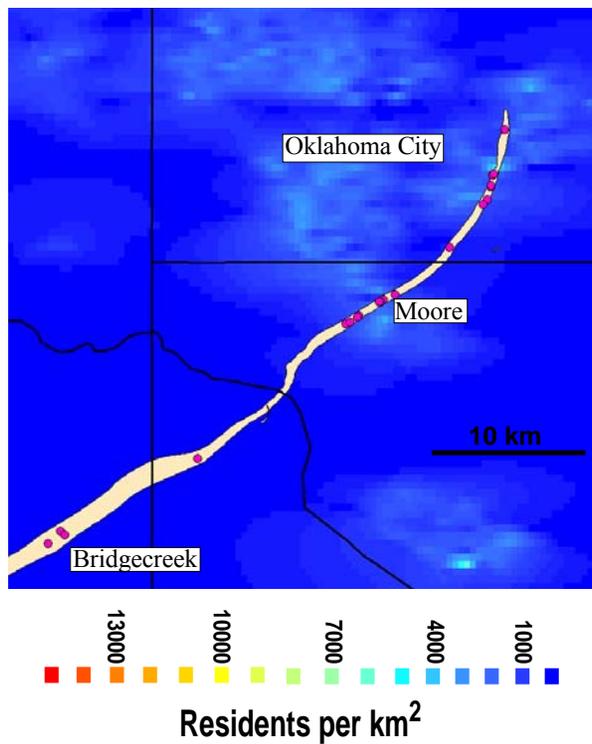

Impacts could be catastrophic:

Deaths > 10,000

Building Damage > \$10 Billion

**Strong
Nighttime
Tornado**

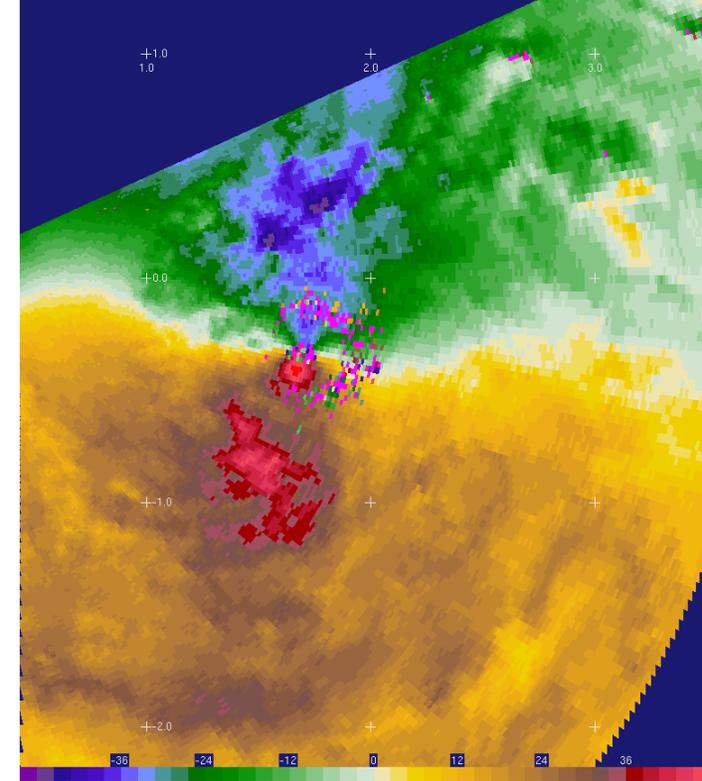

Worst recent urban tornado outbreak was 3 May 1999 in Oklahoma City

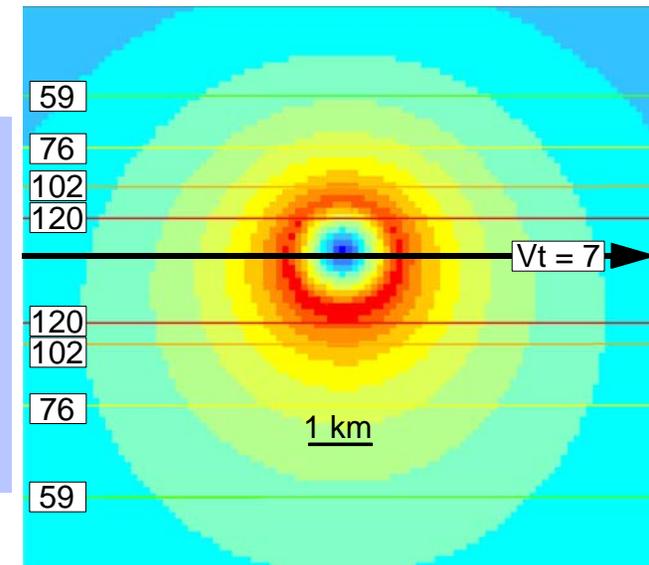

36 dead
\$1 Billion in Damage

But, OKC is very low density urban area
And, tornado mostly passed over rural areas

Using Actual DOW Data From Violent Tornadoes and a Constrained Model

Swaths of Winds Expected From Various Violent, Long-Track Tornadoes can be Calculated

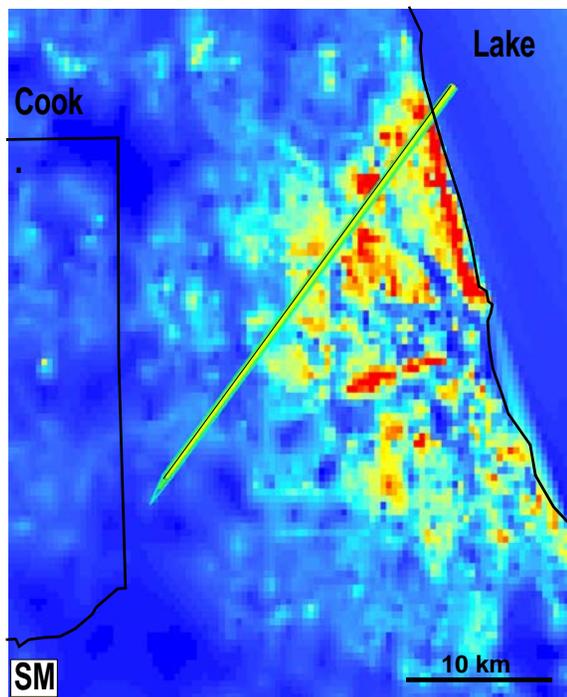

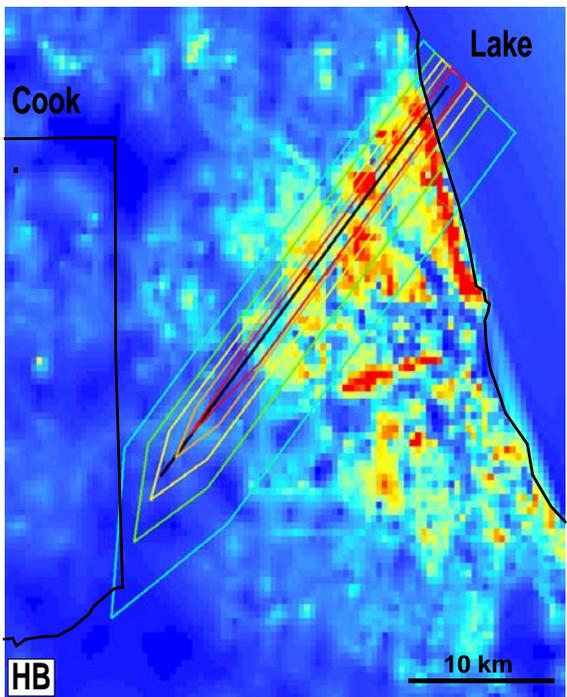

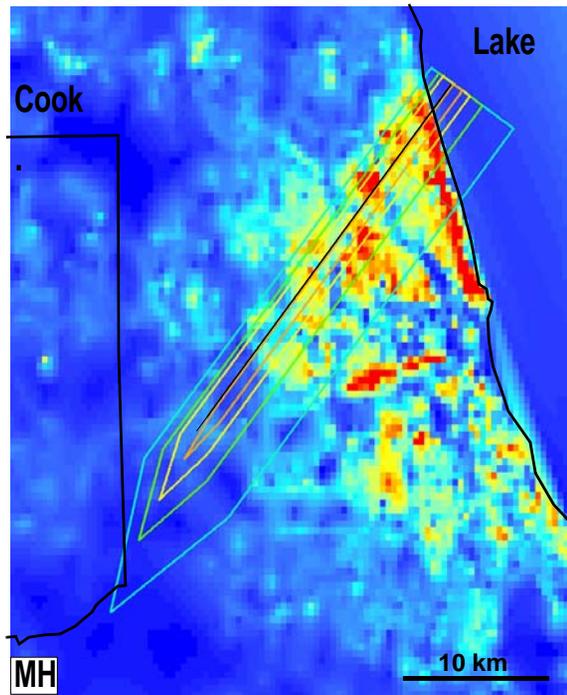

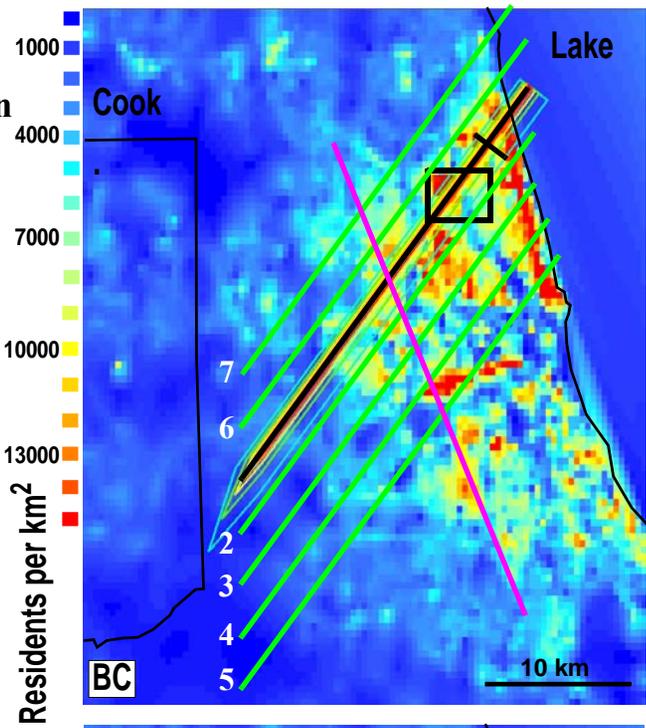

Chicago

Different tornadoes cause different width swaths

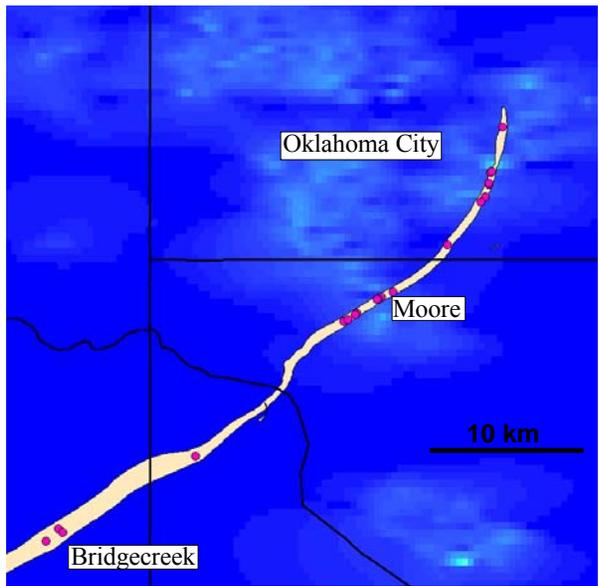

Largest tornadoes, like Mulhall could cause swath 2-5 miles wide of nearly total destruction

Winds in excess of 170 mph, (yellow lines) destroy all single and dual family homes and two to three story apartments

Much higher building densities in Chicago result in many more people under 170 mph winds

Oklahoma City

**Older Residential Neighborhoods
Typical of Some Large Cities
Much Higher Population Density**

Chicago

Oklahoma City

Count People in US Census Blocks

Who experience

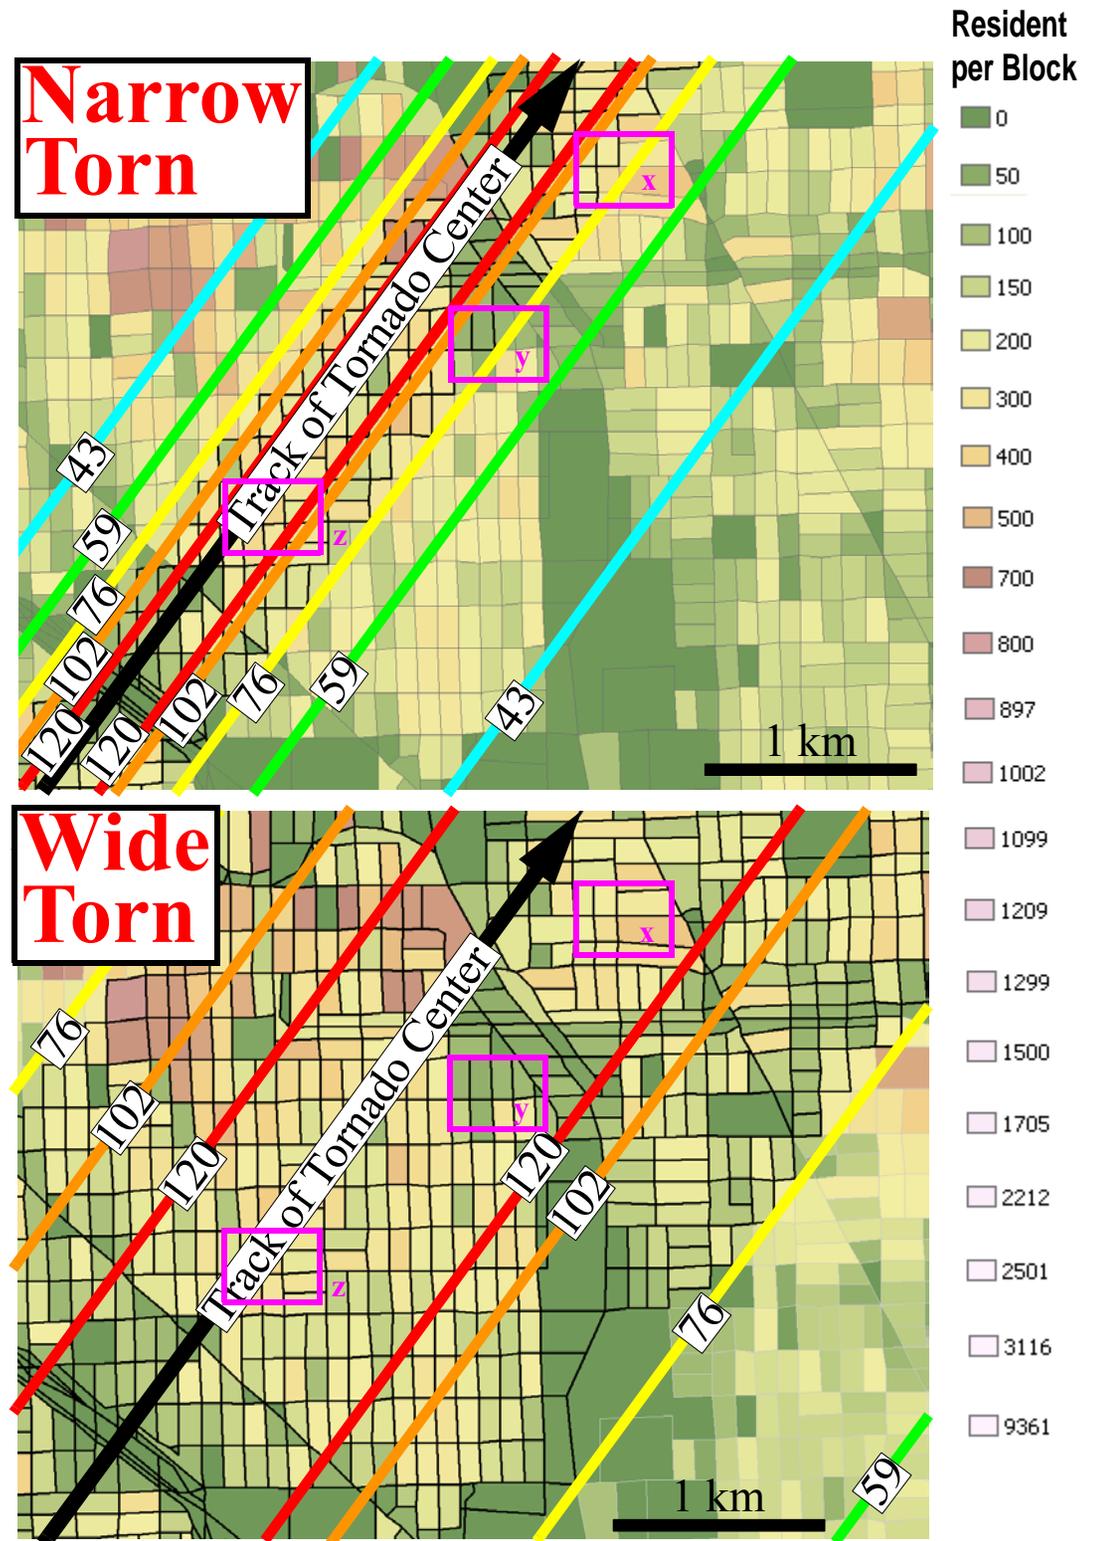

96 mph

132 mph

170 mph

228 mph

268 mph

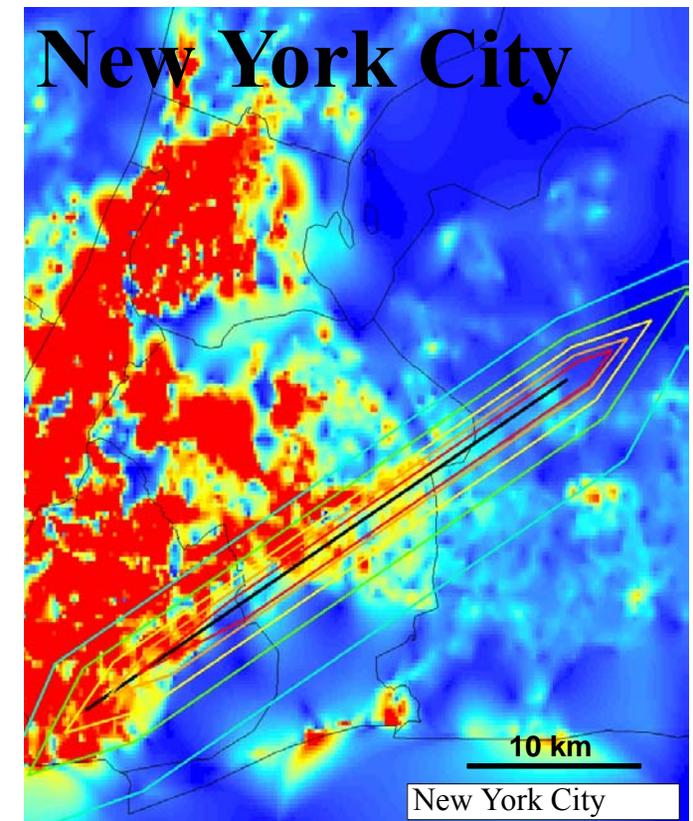

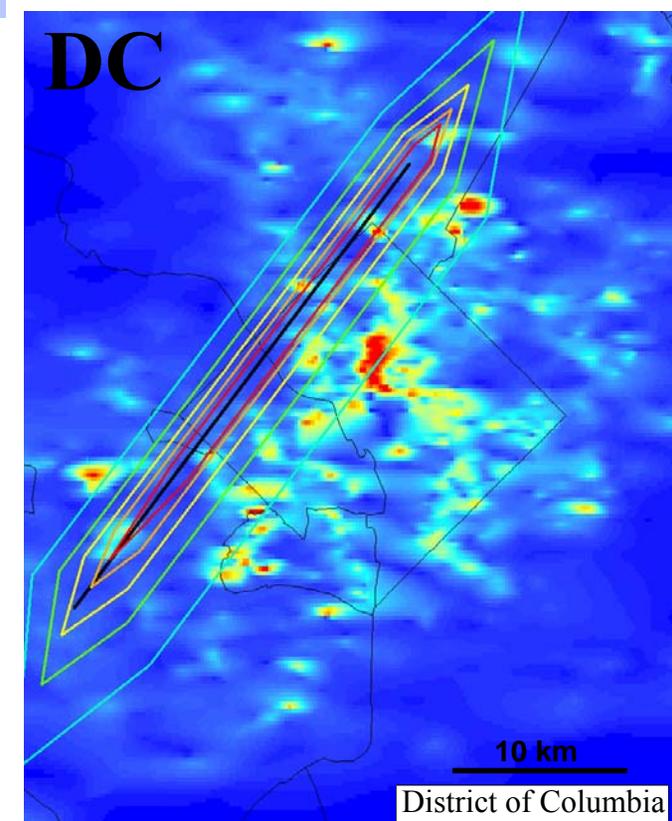

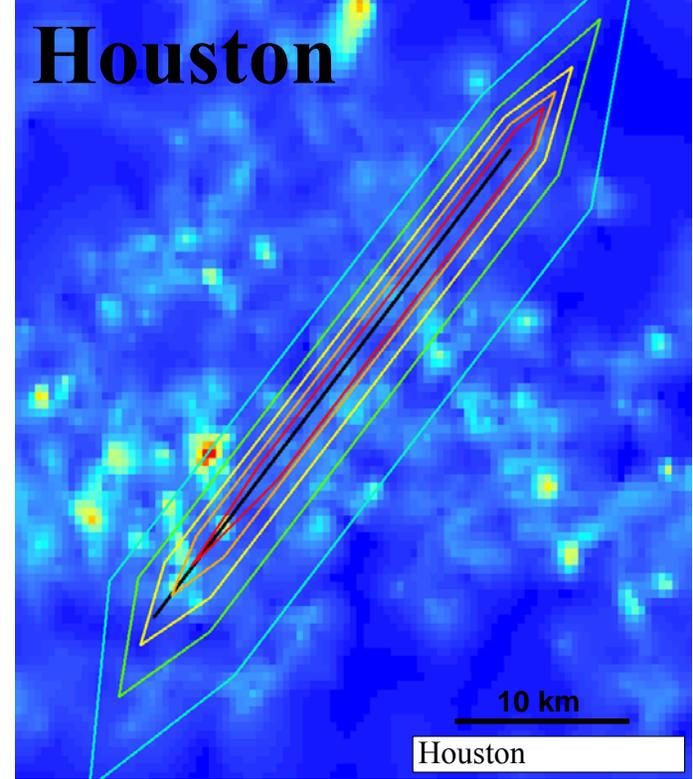

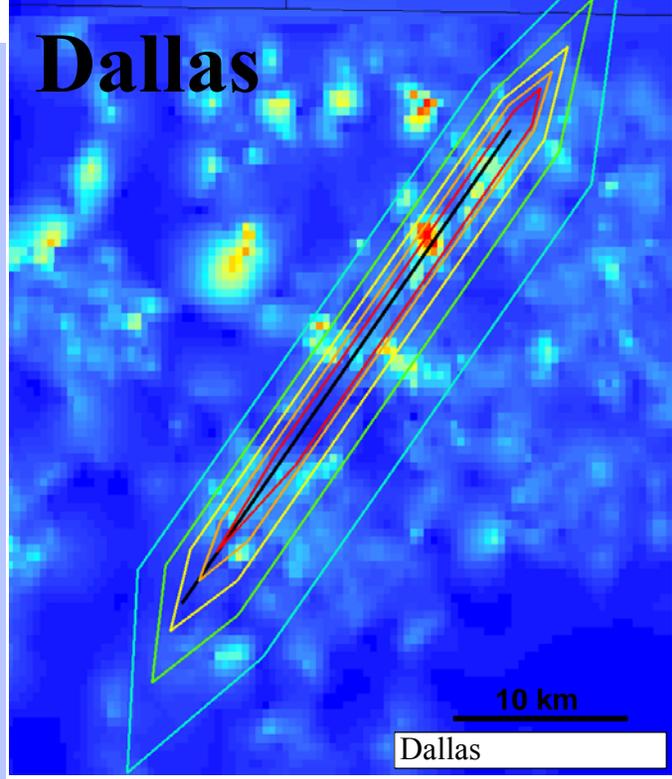

**Major Tornadoes
have Occured
Near**

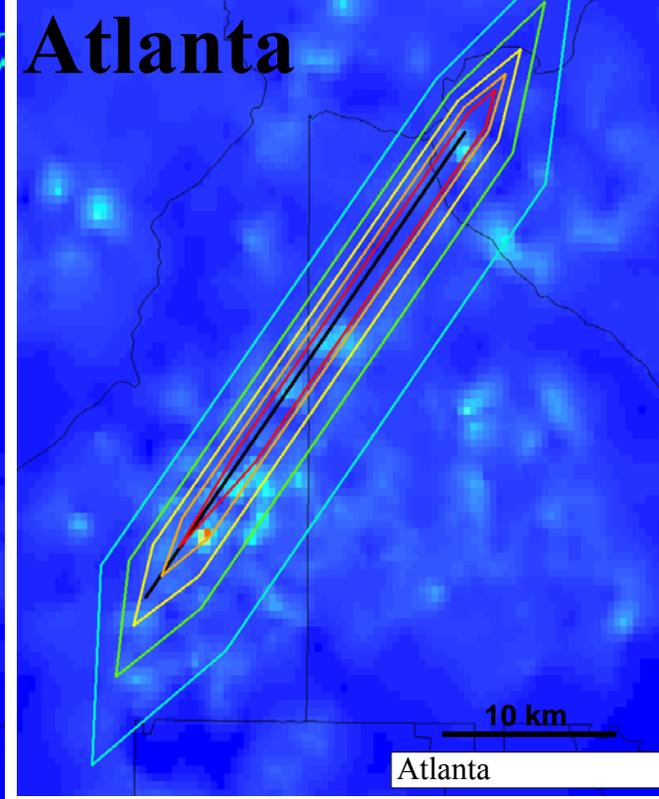

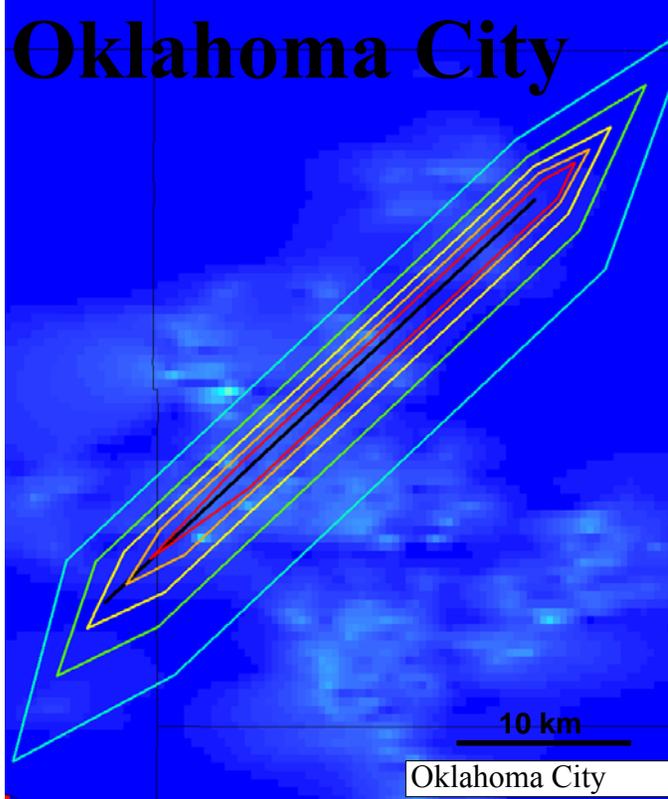

**Dallas
Houston
DC**

and other cities

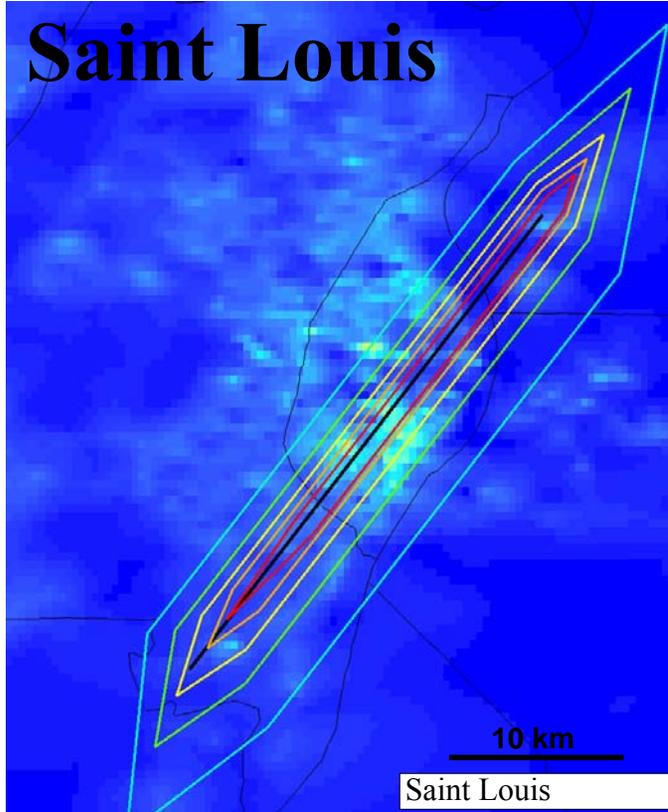

**Potential Impacts
if Violent, Long
Tornado over
Dense Residential
Areas**

**Simulated
tornado passes
over denser
Part of OKC
and is Wider**

**“Rural” parts
of STL, ATL
are more densely
populated than
OKC**

Impact in Chicago

Inside 170 mph wind swath

Homes Destroyed: 10,000 - 152,000 (depends on torn width)

**Residents in
destroyed homes: 30,000 - 450,000**

Deaths: 3,000 - 45,000 (10% fatality rate)

**Hundreds of high rise structures, worth > 10B\$ damaged
by winds > 260 mph**

Impacts in Different Cities

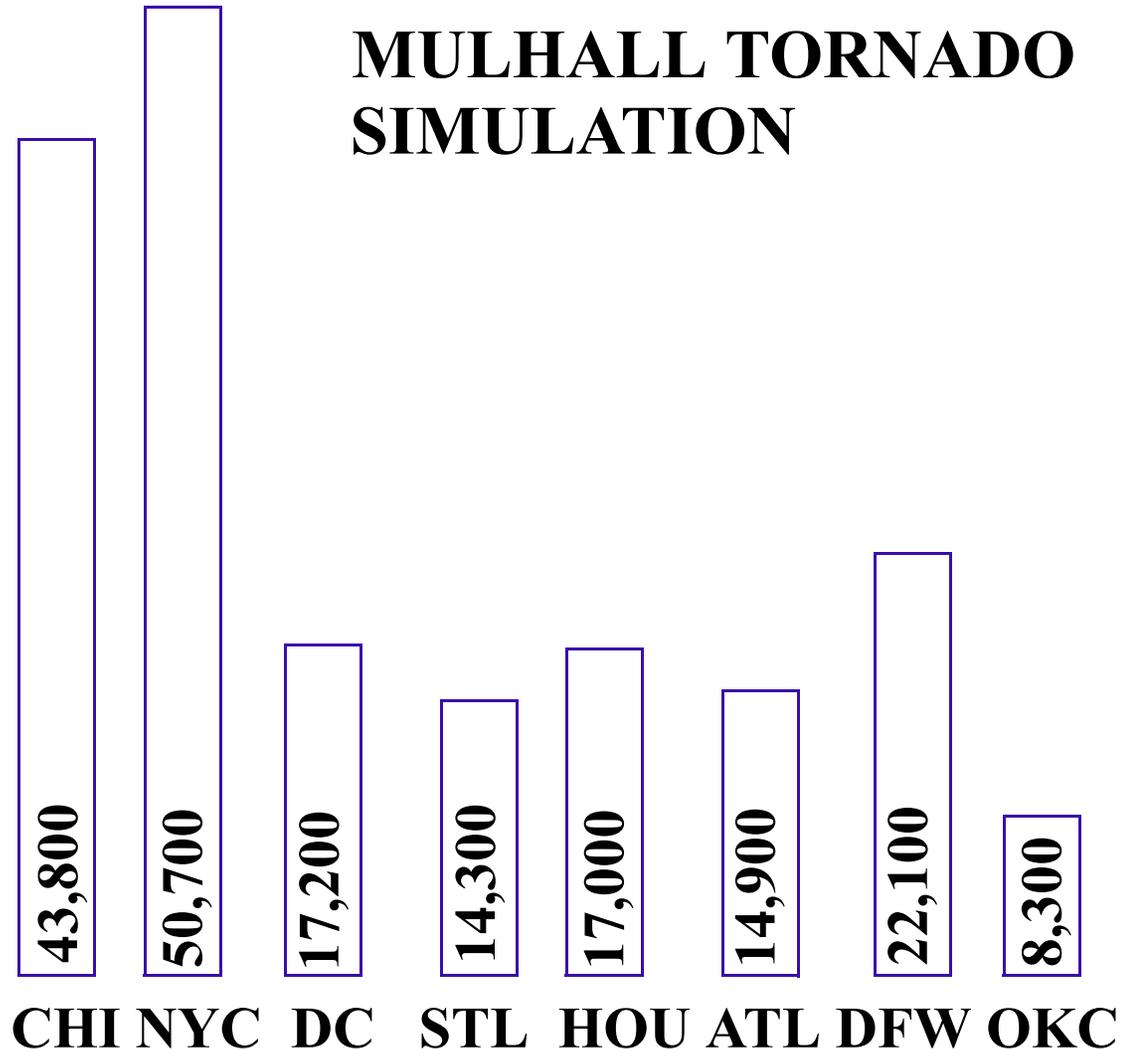

High Housing Density in CHI, NYC results in very high impact, but simulated track avoids city core

Potential impacts of violent tornadoes exceed that of worst hurricanes (Galveston 1900, Katrina) and earthquakes (San Francisco)

Tornadoes can cause more fatalities than hurricanes because:

1. Peak winds are much higher
300 mph vs. about 160 mph (over land)
2. Swath of total destruction is limited to width of hundreds of yards in hurricane surge, but can be a mile wide in large tornado
3. 12 minutes versus 24-36 hours warning means evacuation may be impossible

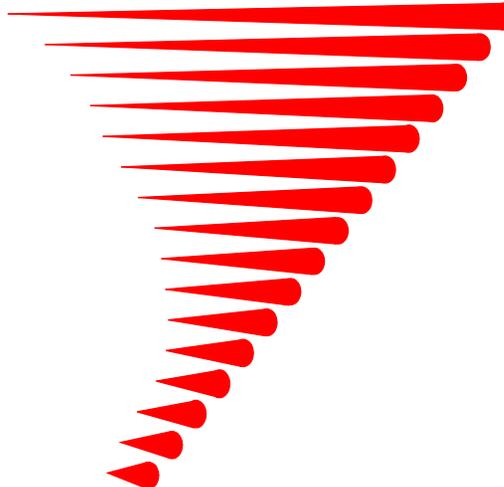

MULHALL TORNADO SIMULATION

Deaths in Low-Rise Residences

Longer warning lead times for violent tornadoes would reduce potential deaths by permitting evacuation.

This can only be achieved by better knowledge through better observations, then an adaptable, targetable observation network.
